#### Abstract

This book provides a self-contained introduction to mathematical methods in quantum mechanics (spectral theory) with applications to Schrödinger operators. The first part covers mathematical foundations of quantum mechanics from self-adjointness, the spectral theorem, quantum dynamics (including Stone's and the RAGE theorem) to perturbation theory for selfadjoint operators.

The second part starts with a detailed study of the free Schrödinger operator respectively position, momentum and angular momentum operators. Then we develop Weyl-Titchmarsh theory for Sturm-Liouville operators and apply it to spherically symmetric problems, in particular to the hydrogen atom. Next we investigate self-adjointness of atomic Schrödinger operators and their essential spectrum, in particular the HVZ theorem. Finally we have a look at scattering theory and prove asymptotic completeness in the short range case.

## Preface

## Overview

The present text was written for my course Schrödinger Operators held at the University of Vienna in winter 1999, summer 2002, summer 2005, and winter 2007. It gives a brief but rather self-contained introduction to the mathematical methods of quantum mechanics with a view towards applications to Schrödinger operators. The applications presented are highly selective and many important and interesting items are not touched upon.

Part 1 is a stripped down introduction to spectral theory of unbounded operators where I try to introduce only those topics which are needed for the applications later on. This has the advantage that you will (hopefully) not get drowned in results which are never used again before you get to the applications. In particular, I am not trying to present an encyclopedic reference. Nevertheless I still feel that the first part should provide a solid background covering many important results which are usually taken for granted in more advanced books and research papers.

My approach is built around the spectral theorem as the central object. Hence I try to get to it as quickly as possible. Moreover, I do not take the detour over bounded operators but I go straight for the unbounded case. In addition, existence of spectral measures is established via the Herglotz theorem rather than the Riesz representation theorem since this approach paves the way for an investigation of spectral types via boundary values of the resolvent as the spectral parameter approaches the real line.

Part 2 starts with the free Schrödinger equation and computes the free resolvent and time evolution. In addition, I discuss position, momentum, and angular momentum operators via algebraic methods. This is usually found in any physics textbook on quantum mechanics, with the only difference that I include some technical details which are typically not found there. Then there is an introduction to one-dimensional models (Sturm-Liouville operators) including generalized eigenfunction expansions (Weyl-Titchmarsh theory) and subordinacy theory from Gilbert and Pearson. These results are applied to compute the spectrum of the hydrogen atom, where again I try to provide some mathematical details not found in physics textbooks. Further topics are nondegeneracy of the ground state, spectra of atoms (the HVZ theorem), and scattering theory (the Enß method).

## Prerequisites

I assume some previous experience with Hilbert spaces and bounded linear operators which should be covered in any basic course on functional analysis. However, while this assumption is reasonable for mathematics students, it might not always be for physics students. For this reason there is a preliminary chapter reviewing all necessary results (including proofs). In addition, there is an appendix (again with proofs) providing all necessary results from measure theory.

## Literature

The present book is highly influenced by the four volumes of Reed and Simon [40]-[43] (see also [14]) and by the book by Weidmann [60] (an extended version of which has recently appeared in two volumes [62], [63], however, only in German). Other books with a similar scope are for example [14], [15], [21], [23], [39], [48], and [55]. For those who want to know more about the physical aspects, I can recommend the classical book by Thirring [58] and the visual guides by Thaller [56], [57]. Further information can be found in the bibliographical notes at the end.

## Reader's guide

There is some intentional overlap between Chapter 0, Chapter 1, and Chapter 2. Hence, provided you have the necessary background, you can start reading in Chapter 1 or even Chapter 2. Chapters 2 and 3 are key
chapters and you should study them in detail (except for Section 2.6 which can be skipped on first reading). Chapter 4 should give you an idea of how the spectral theorem is used. You should have a look at (e.g.) the first section and you can come back to the remaining ones as needed. Chapter 5 contains two key results from quantum dynamics: Stone's theorem and the RAGE theorem. In particular the RAGE theorem shows the connections between long time behavior and spectral types. Finally, Chapter 6 is again of central importance and should be studied in detail.

The chapters in the second part are mostly independent of each other except for Chapter 7, which is a prerequisite for all others except for Chapter 9 .

If you are interested in one-dimensional models (Sturm-Liouville equations), Chapter 9 is all you need.

If you are interested in atoms, read Chapter 7, Chapter 10, and Chapter 11. In particular, you can skip the separation of variables (Sections 10.3 and 10.4, which require Chapter 9) method for computing the eigenvalues of the hydrogen atom, if you are happy with the fact that there are countably many which accumulate at the bottom of the continuous spectrum.

If you are interested in scattering theory, read Chapter 7, the first two sections of Chapter 10, and Chapter 12. Chapter 5 is one of the key prerequisites in this case.

## Updates

The AMS is hosting a web page for this book at

> http://www.ams.org/bookpages/gsm-99/
where updates, corrections, and other material may be found, including a link to material on my own web site:
http://www.mat.univie.ac.at/~gerald/ftp/book-schroe/

## Acknowledgments

I would like to thank Volker Enß for making his lecture notes [18] available to me. Many colleagues and students have made useful suggestions and pointed out mistakes in earlier drafts of this book, in particular: Kerstin Ammann, Jörg Arnberger, Chris Davis, Fritz Gesztesy, Maria HoffmannOstenhof, Zhenyou Huang, Helge Krüger, Katrin Grunert, Wang Lanning, Daniel Lenz, Christine Pfeuffer, Roland Möws, Arnold L. Neidhardt, Harald

Rindler, Johannes Temme, Karl Unterkofler, Joachim Weidmann, and Rudi Weikard.

If you also find an error or if you have comments or suggestions (no matter how small), please let me know.

I have been supported by the Austrian Science Fund (FWF) during much of this writing, most recently under grant Y330.

## Preliminaries

## Chapter 0

## A first look at Banach and Hilbert spaces

I assume that the reader has some basic familiarity with measure theory and functional analysis. For convenience, some facts needed from Banach and $L^{p}$ spaces are reviewed in this chapter. A crash course in measure theory can be found in the Appendix A. If you feel comfortable with terms like Lebesgue $L^{p}$ spaces, Banach space, or bounded linear operator, you can skip this entire chapter. However, you might want to at least browse through it to refresh your memory.

### 0.1. Warm up: Metric and topological spaces

Before we begin, I want to recall some basic facts from metric and topological spaces. I presume that you are familiar with these topics from your calculus course. As a general reference I can warmly recommend Kelly's classical book [26].

A metric space is a space $X$ together with a distance function $d$ : $X \times X \rightarrow \mathbb{R}$ such that
(i) $d(x, y) \geq 0$,
(ii) $d(x, y)=0$ if and only if $x=y$,
(iii) $d(x, y)=d(y, x)$,
(iv) $d(x, z) \leq d(x, y)+d(y, z)$ (triangle inequality).

If (ii) does not hold, $d$ is called a semi-metric. Moreover, it is straightforward to see the inverse triangle inequality (Problem 0.1)

$$
\begin{equation*}
|d(x, y)-d(z, y)| \leq d(x, z) \tag{0.1}
\end{equation*}
$$

Example. Euclidean space $\mathbb{R}^{n}$ together with $d(x, y)=\left(\sum_{k=1}^{n}\left(x_{k}-y_{k}\right)^{2}\right)^{1 / 2}$ is a metric space and so is $\mathbb{C}^{n}$ together with $d(x, y)=\left(\sum_{k=1}^{n}\left|x_{k}-y_{k}\right|^{2}\right)^{1 / 2}$.

The set

$$
\begin{equation*}
B_{r}(x)=\{y \in X \mid d(x, y)<r\} \tag{0.2}
\end{equation*}
$$

is called an open ball around $x$ with radius $r>0$. A point $x$ of some set $U$ is called an interior point of $U$ if $U$ contains some ball around $x$. If $x$ is an interior point of $U$, then $U$ is also called a neighborhood of $x$. A point $x$ is called a limit point of $U$ if $\left(B_{r}(x) \backslash\{x\}\right) \cap U \neq \emptyset$ for every ball around $x$. Note that a limit point $x$ need not lie in $U$, but $U$ must contain points arbitrarily close to $x$.
Example. Consider $\mathbb{R}$ with the usual metric and let $U=(-1,1)$. Then every point $x \in U$ is an interior point of $U$. The points $\pm 1$ are limit points of $U$.

A set consisting only of interior points is called open. The family of open sets $\mathcal{O}$ satisfies the properties
(i) $\emptyset, X \in \mathcal{O}$,
(ii) $O_{1}, O_{2} \in \mathcal{O}$ implies $O_{1} \cap O_{2} \in \mathcal{O}$,
(iii) $\left\{O_{\alpha}\right\} \subseteq \mathcal{O}$ implies $\bigcup_{\alpha} O_{\alpha} \in \mathcal{O}$.

That is, $\mathcal{O}$ is closed under finite intersections and arbitrary unions.
In general, a space $X$ together with a family of sets $\mathcal{O}$, the open sets, satisfying (i)-(iii) is called a topological space. The notions of interior point, limit point, and neighborhood carry over to topological spaces if we replace open ball by open set.

There are usually different choices for the topology. Two usually not very interesting examples are the trivial topology $\mathcal{O}=\{\emptyset, X\}$ and the discrete topology $\mathcal{O}=\mathfrak{P}(X)$ (the powerset of $X$ ). Given two topologies $\mathcal{O}_{1}$ and $\mathcal{O}_{2}$ on $X, \mathcal{O}_{1}$ is called weaker (or coarser) than $\mathcal{O}_{2}$ if and only if $\mathcal{O}_{1} \subseteq \mathcal{O}_{2}$.
Example. Note that different metrics can give rise to the same topology. For example, we can equip $\mathbb{R}^{n}$ (or $\mathbb{C}^{n}$ ) with the Euclidean distance $d(x, y)$ as before or we could also use

$$
\begin{equation*}
\tilde{d}(x, y)=\sum_{k=1}^{n}\left|x_{k}-y_{k}\right| \tag{0.3}
\end{equation*}
$$

Then

$$
\begin{equation*}
\frac{1}{\sqrt{n}} \sum_{k=1}^{n}\left|x_{k}\right| \leq \sqrt{\sum_{k=1}^{n}\left|x_{k}\right|^{2}} \leq \sum_{k=1}^{n}\left|x_{k}\right| \tag{0.4}
\end{equation*}
$$

shows $B_{r / \sqrt{n}}(x) \subseteq \tilde{B}_{r}(x) \subseteq B_{r}(x)$, where $B, \tilde{B}$ are balls computed using $d$, $\tilde{d}$, respectively.

Example. We can always replace a metric $d$ by the bounded metric

$$
\begin{equation*}
\tilde{d}(x, y)=\frac{d(x, y)}{1+d(x, y)} \tag{0.5}
\end{equation*}
$$

without changing the topology.
Every subspace $Y$ of a topological space $X$ becomes a topological space of its own if we call $O \subseteq Y$ open if there is some open set $\tilde{O} \subseteq X$ such that $O=\tilde{O} \cap Y$ (induced topology).
Example. The set $(0,1] \subseteq \mathbb{R}$ is not open in the topology of $X=\mathbb{R}$, but it is open in the induced topology when considered as a subset of $Y=[-1,1]$.

A family of open sets $\mathcal{B} \subseteq \mathcal{O}$ is called a base for the topology if for each $x$ and each neighborhood $U(x)$, there is some set $O \in \mathcal{B}$ with $x \in O \subseteq U(x)$. Since an open set $O$ is a neighborhood of every one of its points, it can be written as $O=\bigcup_{O \supseteq \tilde{O} \in \mathcal{B}} \tilde{O}$ and we have
Lemma 0.1. If $\mathcal{B} \subseteq \mathcal{O}$ is a base for the topology, then every open set can be written as a union of elements from $\mathcal{B}$.

If there exists a countable base, then $X$ is called second countable.
Example. By construction the open balls $B_{1 / n}(x)$ are a base for the topology in a metric space. In the case of $\mathbb{R}^{n}\left(\right.$ or $\left.\mathbb{C}^{n}\right)$ it even suffices to take balls with rational center and hence $\mathbb{R}^{n}$ (and $\mathbb{C}^{n}$ ) is second countable.

A topological space is called a Hausdorff space if for two different points there are always two disjoint neighborhoods.
Example. Any metric space is a Hausdorff space: Given two different points $x$ and $y$, the balls $B_{d / 2}(x)$ and $B_{d / 2}(y)$, where $d=d(x, y)>0$, are disjoint neighborhoods (a semi-metric space will not be Hausdorff).

The complement of an open set is called a closed set. It follows from de Morgan's rules that the family of closed sets $\mathcal{C}$ satisfies
(i) $\emptyset, X \in \mathcal{C}$,
(ii) $C_{1}, C_{2} \in \mathcal{C}$ implies $C_{1} \cup C_{2} \in \mathcal{C}$,
(iii) $\left\{C_{\alpha}\right\} \subseteq \mathcal{C}$ implies $\bigcap_{\alpha} C_{\alpha} \in \mathcal{C}$.

That is, closed sets are closed under finite unions and arbitrary intersections.
The smallest closed set containing a given set $U$ is called the closure

$$
\begin{equation*}
\bar{U}=\bigcap_{C \in \mathcal{C}, U \subseteq C} C, \tag{0.6}
\end{equation*}
$$

and the largest open set contained in a given set $U$ is called the interior

$$
\begin{equation*}
U^{\circ}=\bigcup_{O \in \mathcal{O}, O \subseteq U} O . \tag{0.7}
\end{equation*}
$$

We can define interior and limit points as before by replacing the word ball by open set. Then it is straightforward to check
Lemma 0.2. Let $X$ be a topological space. Then the interior of $U$ is the set of all interior points of $U$ and the closure of $U$ is the union of $U$ with all limit points of $U$.

A sequence $\left(x_{n}\right)_{n=1}^{\infty} \subseteq X$ is said to converge to some point $x \in X$ if $d\left(x, x_{n}\right) \rightarrow 0$. We write $\lim _{n \rightarrow \infty} x_{n}=x$ as usual in this case. Clearly the limit is unique if it exists (this is not true for a semi-metric).

Every convergent sequence is a Cauchy sequence; that is, for every $\varepsilon>0$ there is some $N \in \mathbb{N}$ such that

$$
\begin{equation*}
d\left(x_{n}, x_{m}\right) \leq \varepsilon, \quad n, m \geq N . \tag{0.8}
\end{equation*}
$$

If the converse is also true, that is, if every Cauchy sequence has a limit, then $X$ is called complete.
Example. Both $\mathbb{R}^{n}$ and $\mathbb{C}^{n}$ are complete metric spaces.
A point $x$ is clearly a limit point of $U$ if and only if there is some sequence $x_{n} \in U \backslash\{x\}$ converging to $x$. Hence
Lemma 0.3. A closed subset of a complete metric space is again a complete metric space.

Note that convergence can also be equivalently formulated in terms of topological terms: A sequence $x_{n}$ converges to $x$ if and only if for every neighborhood $U$ of $x$ there is some $N \in \mathbb{N}$ such that $x_{n} \in U$ for $n \geq N$. In a Hausdorff space the limit is unique.

A set $U$ is called dense if its closure is all of $X$, that is, if $\bar{U}=X$. A metric space is called separable if it contains a countable dense set. Note that $X$ is separable if and only if it is second countable as a topological space.

Lemma 0.4. Let $X$ be a separable metric space. Every subset of $X$ is again separable.

Proof. Let $A=\left\{x_{n}\right\}_{n \in \mathbb{N}}$ be a dense set in $X$. The only problem is that $A \cap Y$ might contain no elements at all. However, some elements of $A$ must be at least arbitrarily close: Let $J \subseteq \mathbb{N}^{2}$ be the set of all pairs $(n, m)$ for which $B_{1 / m}\left(x_{n}\right) \cap Y \neq \emptyset$ and choose some $y_{n, m} \in B_{1 / m}\left(x_{n}\right) \cap Y$ for all $(n, m) \in J$. Then $B=\left\{y_{n, m}\right\}_{(n, m) \in J} \subseteq Y$ is countable. To see that $B$ is
dense, choose $y \in Y$. Then there is some sequence $x_{n_{k}}$ with $d\left(x_{n_{k}}, y\right)<1 / k$. Hence $\left(n_{k}, k\right) \in J$ and $d\left(y_{n_{k}, k}, y\right) \leq d\left(y_{n_{k}, k}, x_{n_{k}}\right)+d\left(x_{n_{k}}, y\right) \leq 2 / k \rightarrow 0$.

A function between metric spaces $X$ and $Y$ is called continuous at a point $x \in X$ if for every $\varepsilon>0$ we can find a $\delta>0$ such that

$$
\begin{equation*}
d_{Y}(f(x), f(y)) \leq \varepsilon \quad \text { if } \quad d_{X}(x, y)<\delta . \tag{0.9}
\end{equation*}
$$

If $f$ is continuous at every point, it is called continuous.
Lemma 0.5. Let $X, Y$ be metric spaces and $f: X \rightarrow Y$. The following are equivalent:
(i) $f$ is continuous at $x$ (i.e, (0.9) holds).
(ii) $f\left(x_{n}\right) \rightarrow f(x)$ whenever $x_{n} \rightarrow x$.
(iii) For every neighborhood $V$ of $f(x), f^{-1}(V)$ is a neighborhood of $x$.

Proof. (i) $\Rightarrow$ (ii) is obvious. (ii) $\Rightarrow$ (iii): If (iii) does not hold, there is a neighborhood $V$ of $f(x)$ such that $B_{\delta}(x) \nsubseteq f^{-1}(V)$ for every $\delta$. Hence we can choose a sequence $x_{n} \in B_{1 / n}(x)$ such that $f\left(x_{n}\right) \notin f^{-1}(V)$. Thus $x_{n} \rightarrow x$ but $f\left(x_{n}\right) \nrightarrow f(x)$. (iii) $\Rightarrow$ (i): Choose $V=B_{\varepsilon}(f(x))$ and observe that by (iii), $B_{\delta}(x) \subseteq f^{-1}(V)$ for some $\delta$.

The last item implies that $f$ is continuous if and only if the inverse image of every open (closed) set is again open (closed).

Note: In a topological space, (iii) is used as the definition for continuity. However, in general (ii) and (iii) will no longer be equivalent unless one uses generalized sequences, so-called nets, where the index set $\mathbb{N}$ is replaced by arbitrary directed sets.

The support of a function $f: X \rightarrow \mathbb{C}^{n}$ is the closure of all points $x$ for which $f(x)$ does not vanish; that is,

$$
\begin{equation*}
\operatorname{supp}(f)=\overline{\{x \in X \mid f(x) \neq 0\}} . \tag{0.10}
\end{equation*}
$$

If $X$ and $Y$ are metric spaces, then $X \times Y$ together with

$$
\begin{equation*}
d\left(\left(x_{1}, y_{1}\right),\left(x_{2}, y_{2}\right)\right)=d_{X}\left(x_{1}, x_{2}\right)+d_{Y}\left(y_{1}, y_{2}\right) \tag{0.11}
\end{equation*}
$$

is a metric space. A sequence $\left(x_{n}, y_{n}\right)$ converges to $(x, y)$ if and only if $x_{n} \rightarrow x$ and $y_{n} \rightarrow y$. In particular, the projections onto the first $(x, y) \mapsto x$, respectively, onto the second $(x, y) \mapsto y$, coordinate are continuous.

In particular, by the inverse triangle inequality (0.1),

$$
\begin{equation*}
\left|d\left(x_{n}, y_{n}\right)-d(x, y)\right| \leq d\left(x_{n}, x\right)+d\left(y_{n}, y\right), \tag{0.12}
\end{equation*}
$$

we see that $d: X \times X \rightarrow \mathbb{R}$ is continuous.

Example. If we consider $\mathbb{R} \times \mathbb{R}$, we do not get the Euclidean distance of $\mathbb{R}^{2}$ unless we modify (0.11) as follows:

$$
\begin{equation*}
\tilde{d}\left(\left(x_{1}, y_{1}\right),\left(x_{2}, y_{2}\right)\right)=\sqrt{d_{X}\left(x_{1}, x_{2}\right)^{2}+d_{Y}\left(y_{1}, y_{2}\right)^{2}} . \tag{0.13}
\end{equation*}
$$

As noted in our previous example, the topology (and thus also convergence/continuity) is independent of this choice.

If $X$ and $Y$ are just topological spaces, the product topology is defined by calling $O \subseteq X \times Y$ open if for every point $(x, y) \in O$ there are open neighborhoods $U$ of $x$ and $V$ of $y$ such that $U \times V \subseteq O$. In the case of metric spaces this clearly agrees with the topology defined via the product metric (0.11).

A cover of a set $Y \subseteq X$ is a family of sets $\left\{U_{\alpha}\right\}$ such that $Y \subseteq \bigcup_{\alpha} U_{\alpha}$. A cover is called open if all $U_{\alpha}$ are open. Any subset of $\left\{U_{\alpha}\right\}$ which still covers $Y$ is called a subcover.

Lemma 0.6 (Lindelöf). If $X$ is second countable, then every open cover has a countable subcover.

Proof. Let $\left\{U_{\alpha}\right\}$ be an open cover for $Y$ and let $\mathcal{B}$ be a countable base. Since every $U_{\alpha}$ can be written as a union of elements from $\mathcal{B}$, the set of all $B \in \mathcal{B}$ which satisfy $B \subseteq U_{\alpha}$ for some $\alpha$ form a countable open cover for $Y$. Moreover, for every $B_{n}$ in this set we can find an $\alpha_{n}$ such that $B_{n} \subseteq U_{\alpha_{n}}$. By construction $\left\{U_{\alpha_{n}}\right\}$ is a countable subcover.

A subset $K \subset X$ is called compact if every open cover has a finite subcover.

Lemma 0.7. A topological space is compact if and only if it has the finite intersection property: The intersection of a family of closed sets is empty if and only if the intersection of some finite subfamily is empty.

Proof. By taking complements, to every family of open sets there is a corresponding family of closed sets and vice versa. Moreover, the open sets are a cover if and only if the corresponding closed sets have empty intersection.

A subset $K \subset X$ is called sequentially compact if every sequence has a convergent subsequence.

Lemma 0.8. Let $X$ be a topological space.
(i) The continuous image of a compact set is compact.
(ii) Every closed subset of a compact set is compact.
(iii) If $X$ is Hausdorff, any compact set is closed.
(iv) The product of finitely many compact sets is compact.
(v) A compact set is also sequentially compact.

Proof. (i) Observe that if $\left\{O_{\alpha}\right\}$ is an open cover for $f(Y)$, then $\left\{f^{-1}\left(O_{\alpha}\right)\right\}$ is one for $Y$.
(ii) Let $\left\{O_{\alpha}\right\}$ be an open cover for the closed subset $Y$. Then $\left\{O_{\alpha}\right\} \cup$ $\{X \backslash Y\}$ is an open cover for $X$.
(iii) Let $Y \subseteq X$ be compact. We show that $X \backslash Y$ is open. Fix $x \in X \backslash Y$ (if $Y=X$, there is nothing to do). By the definition of Hausdorff, for every $y \in Y$ there are disjoint neighborhoods $V(y)$ of $y$ and $U_{y}(x)$ of $x$. By compactness of $Y$, there are $y_{1}, \ldots, y_{n}$ such that the $V\left(y_{j}\right)$ cover $Y$. But then $U(x)=\bigcap_{j=1}^{n} U_{y_{j}}(x)$ is a neighborhood of $x$ which does not intersect $Y$.
(iv) Let $\left\{O_{\alpha}\right\}$ be an open cover for $X \times Y$. For every $(x, y) \in X \times Y$ there is some $\alpha(x, y)$ such that $(x, y) \in O_{\alpha(x, y)}$. By definition of the product topology there is some open rectangle $U(x, y) \times V(x, y) \subseteq O_{\alpha(x, y)}$. Hence for fixed $x,\{V(x, y)\}_{y \in Y}$ is an open cover of $Y$. Hence there are finitely many points $y_{k}(x)$ such that the $V\left(x, y_{k}(x)\right)$ cover $Y$. Set $U(x)=\bigcap_{k} U\left(x, y_{k}(x)\right)$. Since finite intersections of open sets are open, $\{U(x)\}_{x \in X}$ is an open cover and there are finitely many points $x_{j}$ such that the $U\left(x_{j}\right)$ cover $X$. By construction, the $U\left(x_{j}\right) \times V\left(x_{j}, y_{k}\left(x_{j}\right)\right) \subseteq O_{\alpha\left(x_{j}, y_{k}\left(x_{j}\right)\right)}$ cover $X \times Y$.
(v) Let $x_{n}$ be a sequence which has no convergent subsequence. Then $K=\left\{x_{n}\right\}$ has no limit points and is hence compact by (ii). For every $n$ there is a ball $B_{\varepsilon_{n}}\left(x_{n}\right)$ which contains only finitely many elements of $K$. However, finitely many suffice to cover $K$, a contradiction.

In a metric space compact and sequentially compact are equivalent.
Lemma 0.9. Let $X$ be a metric space. Then a subset is compact if and only if it is sequentially compact.

Proof. By item (v) of the previous lemma it suffices to show that $X$ is compact if it is sequentially compact.

First of all note that every cover of open balls with fixed radius $\varepsilon>0$ has a finite subcover since if this were false we could construct a sequence $x_{n} \in X \backslash \bigcup_{m=1}^{n-1} B_{\varepsilon}\left(x_{m}\right)$ such that $d\left(x_{n}, x_{m}\right)>\varepsilon$ for $m<n$.

In particular, we are done if we can show that for every open cover $\left\{O_{\alpha}\right\}$ there is some $\varepsilon>0$ such that for every $x$ we have $B_{\varepsilon}(x) \subseteq O_{\alpha}$ for some $\alpha=\alpha(x)$. Indeed, choosing $\left\{x_{k}\right\}_{k=1}^{n}$ such that $B_{\varepsilon}\left(x_{k}\right)$ is a cover, we have that $O_{\alpha\left(x_{k}\right)}$ is a cover as well.

So it remains to show that there is such an $\varepsilon$. If there were none, for every $\varepsilon>0$ there must be an $x$ such that $B_{\varepsilon}(x) \nsubseteq O_{\alpha}$ for every $\alpha$. Choose
$\varepsilon=\frac{1}{n}$ and pick a corresponding $x_{n}$. Since $X$ is sequentially compact, it is no restriction to assume $x_{n}$ converges (after maybe passing to a subsequence). Let $x=\lim x_{n}$. Then $x$ lies in some $O_{\alpha}$ and hence $B_{\varepsilon}(x) \subseteq O_{\alpha}$. But choosing $n$ so large that $\frac{1}{n}<\frac{\varepsilon}{2}$ and $d\left(x_{n}, x\right)<\frac{\varepsilon}{2}$, we have $B_{1 / n}\left(x_{n}\right) \subseteq B_{\varepsilon}(x) \subseteq O_{\alpha}$, contradicting our assumption.

Please also recall the Heine-Borel theorem:
Theorem 0.10 (Heine-Borel). In $\mathbb{R}^{n}$ (or $\mathbb{C}^{n}$ ) a set is compact if and only if it is bounded and closed.

Proof. By Lemma 0.8 (ii) and (iii) it suffices to show that a closed interval in $I \subseteq \mathbb{R}$ is compact. Moreover, by Lemma 0.9 it suffices to show that every sequence in $I=[a, b]$ has a convergent subsequence. Let $x_{n}$ be our sequence and divide $I=\left[a, \frac{a+b}{2}\right] \cup\left[\frac{a+b}{2}, b\right]$. Then at least one of these two intervals, call it $I_{1}$, contains infinitely many elements of our sequence. Let $y_{1}=x_{n_{1}}$ be the first one. Subdivide $I_{1}$ and pick $y_{2}=x_{n_{2}}$, with $n_{2}>n_{1}$ as before. Proceeding like this, we obtain a Cauchy sequence $y_{n}$ (note that by construction $I_{n+1} \subseteq I_{n}$ and hence $\left|y_{n}-y_{m}\right| \leq \frac{b-a}{n}$ for $m \geq n$ ).

A topological space is called locally compact if every point has a compact neighborhood.
Example. $\mathbb{R}^{n}$ is locally compact.
The distance between a point $x \in X$ and a subset $Y \subseteq X$ is

$$
\begin{equation*}
\operatorname{dist}(x, Y)=\inf _{y \in Y} d(x, y) \tag{0.14}
\end{equation*}
$$

Note that $x$ is a limit point of $Y$ if and only if $\operatorname{dist}(x, Y)=0$.
Lemma 0.11. Let $X$ be a metric space. Then

$$
\begin{equation*}
|\operatorname{dist}(x, Y)-\operatorname{dist}(z, Y)| \leq d(x, z) \tag{0.15}
\end{equation*}
$$

In particular, $x \mapsto \operatorname{dist}(x, Y)$ is continuous.
Proof. Taking the infimum in the triangle inequality $d(x, y) \leq d(x, z)+$ $d(z, y)$ shows $\operatorname{dist}(x, Y) \leq d(x, z)+\operatorname{dist}(z, Y)$. Hence $\operatorname{dist}(x, Y)-\operatorname{dist}(z, Y) \leq$ $d(x, z)$. Interchanging $x$ and $z$ shows $\operatorname{dist}(z, Y)-\operatorname{dist}(x, Y) \leq d(x, z)$.

Lemma 0.12 (Urysohn). Suppose $C_{1}$ and $C_{2}$ are disjoint closed subsets of a metric space $X$. Then there is a continuous function $f: X \rightarrow[0,1]$ such that $f$ is zero on $C_{1}$ and one on $C_{2}$.

If $X$ is locally compact and $C_{1}$ is compact, one can choose $f$ with compact support.

Proof. To prove the first claim, set $f(x)=\frac{\operatorname{dist}\left(x, C_{2}\right)}{\operatorname{dist}\left(x, C_{1}\right)+\operatorname{dist}\left(x, C_{2}\right)}$. For the second claim, observe that there is an open set $O$ such that $\bar{O}$ is compact and $C_{1} \subset O \subset \bar{O} \subset X \backslash C_{2}$. In fact, for every $x$, there is a ball $B_{\varepsilon}(x)$ such that $\overline{B_{\varepsilon}(x)}$ is compact and $\overline{B_{\varepsilon}(x)} \subset X \backslash C_{2}$. Since $C_{1}$ is compact, finitely many of them cover $C_{1}$ and we can choose the union of those balls to be $O$. Now replace $C_{2}$ by $X \backslash \bar{O}$.

Note that Urysohn's lemma implies that a metric space is normal; that is, for any two disjoint closed sets $C_{1}$ and $C_{2}$, there are disjoint open sets $O_{1}$ and $O_{2}$ such that $C_{j} \subseteq O_{j}, j=1,2$. In fact, choose $f$ as in Urysohn's lemma and set $O_{1}=f^{-1}([0,1 / 2))$, respectively, $O_{2}=f^{-1}((1 / 2,1])$.
Lemma 0.13. Let $X$ be a locally compact metric space. Suppose $K$ is a compact set and $\left\{O_{j}\right\}_{j=1}^{n}$ an open cover. Then there is a partition of unity for $K$ subordinate to this cover; that is, there are continuous functions $h_{j}: X \rightarrow[0,1]$ such that $h_{j}$ has compact support contained in $O_{j}$ and

$$
\begin{equation*}
\sum_{j=1}^{n} h_{j}(x) \leq 1 \tag{0.16}
\end{equation*}
$$

with equality for $x \in K$.
Proof. For every $x \in K$ there is some $\varepsilon$ and some $j$ such that $\overline{B_{\varepsilon}(x)} \subseteq O_{j}$. By compactness of $K$, finitely many of these balls cover $K$. Let $K_{j}$ be the union of those balls which lie inside $O_{j}$. By Urysohn's lemma there are functions $g_{j}: X \rightarrow[0,1]$ such that $g_{j}=1$ on $K_{j}$ and $g_{j}=0$ on $X \backslash O_{j}$. Now set

$$
\begin{equation*}
h_{j}=g_{j} \prod_{k=1}^{j-1}\left(1-g_{k}\right) \tag{0.17}
\end{equation*}
$$

Then $h_{j}: X \rightarrow[0,1]$ has compact support contained in $O_{j}$ and

$$
\begin{equation*}
\sum_{j=1}^{n} h_{j}(x)=1-\prod_{j=1}^{n}\left(1-g_{j}(x)\right) \tag{0.18}
\end{equation*}
$$

shows that the sum is one for $x \in K$, since $x \in K_{j}$ for some $j$ implies $g_{j}(x)=1$ and causes the product to vanish.
Problem 0.1. Show that $|d(x, y)-d(z, y)| \leq d(x, z)$.
Problem 0.2. Show the quadrangle inequality $\left|d(x, y)-d\left(x^{\prime}, y^{\prime}\right)\right| \leq$ $d\left(x, x^{\prime}\right)+d\left(y, y^{\prime}\right)$.
Problem 0.3. Let $X$ be some space together with a sequence of distance functions $d_{n}, n \in \mathbb{N}$. Show that

$$
d(x, y)=\sum_{n=1}^{\infty} \frac{1}{2^{n}} \frac{d_{n}(x, y)}{1+d_{n}(x, y)}
$$

is again a distance function.
Problem 0.4. Show that the closure satisfies $\overline{\bar{U}}=\bar{U}$.
Problem 0.5. Let $U \subseteq V$ be subsets of a metric space $X$. Show that if $U$ is dense in $V$ and $V$ is dense in $X$, then $U$ is dense in $X$.

Problem 0.6. Show that any open set $O \subseteq \mathbb{R}$ can be written as a countable union of disjoint intervals. (Hint: Let $\left\{I_{\alpha}\right\}$ be the set of all maximal subintervals of $O$; that is, $I_{\alpha} \subseteq O$ and there is no other subinterval of $O$ which contains $I_{\alpha}$. Then this is a cover of disjoint intervals which has a countable subcover.)

### 0.2. The Banach space of continuous functions

Now let us have a first look at Banach spaces by investigating the set of continuous functions $C(I)$ on a compact interval $I=[a, b] \subset \mathbb{R}$. Since we want to handle complex models, we will always consider complex-valued functions!

One way of declaring a distance, well-known from calculus, is the maximum norm:

$$
\begin{equation*}
\|f(x)-g(x)\|_{\infty}=\max _{x \in I}|f(x)-g(x)| . \tag{0.19}
\end{equation*}
$$

It is not hard to see that with this definition $C(I)$ becomes a normed linear space:

A normed linear space $X$ is a vector space $X$ over $\mathbb{C}$ (or $\mathbb{R}$ ) with a real-valued function (the norm) $\|$.$\| such that$

- $\|f\| \geq 0$ for all $f \in X$ and $\|f\|=0$ if and only if $f=0$,
- $\|\alpha f\|=|\alpha|\|f\|$ for all $\alpha \in \mathbb{C}$ and $f \in X$, and
- $\|f+g\| \leq\|f\|+\|g\|$ for all $f, g \in X$ (triangle inequality).

From the triangle inequality we also get the inverse triangle inequality (Problem 0.7)

$$
\begin{equation*}
|\|f\|-\|g\|| \leq\|f-g\| . \tag{0.20}
\end{equation*}
$$

Once we have a norm, we have a distance $d(f, g)=\|f-g\|$ and hence we know when a sequence of vectors $f_{n}$ converges to a vector $f$. We will write $f_{n} \rightarrow f$ or $\lim _{n \rightarrow \infty} f_{n}=f$, as usual, in this case. Moreover, a mapping $F: X \rightarrow Y$ between two normed spaces is called continuous if $f_{n} \rightarrow f$ implies $F\left(f_{n}\right) \rightarrow F(f)$. In fact, it is not hard to see that the norm, vector addition, and multiplication by scalars are continuous (Problem 0.8).

In addition to the concept of convergence we have also the concept of a Cauchy sequence and hence the concept of completeness: A normed
space is called complete if every Cauchy sequence has a limit. A complete normed space is called a Banach space.
Example. The space $\ell^{1}(\mathbb{N})$ of all sequences $a=\left(a_{j}\right)_{j=1}^{\infty}$ for which the norm

$$
\begin{equation*}
\|a\|_{1}=\sum_{j=1}^{\infty}\left|a_{j}\right| \tag{0.21}
\end{equation*}
$$

is finite is a Banach space.
To show this, we need to verify three things: (i) $\ell^{1}(\mathbb{N})$ is a vector space that is closed under addition and scalar multiplication, (ii) $\|.\|_{1}$ satisfies the three requirements for a norm, and (iii) $\ell^{1}(\mathbb{N})$ is complete.

First of all observe

$$
\begin{equation*}
\sum_{j=1}^{k}\left|a_{j}+b_{j}\right| \leq \sum_{j=1}^{k}\left|a_{j}\right|+\sum_{j=1}^{k}\left|b_{j}\right| \leq\|a\|_{1}+\|b\|_{1} \tag{0.22}
\end{equation*}
$$

for any finite $k$. Letting $k \rightarrow \infty$, we conclude that $\ell^{1}(\mathbb{N})$ is closed under addition and that the triangle inequality holds. That $\ell^{1}(\mathbb{N})$ is closed under scalar multiplication and the two other properties of a norm are straightforward. It remains to show that $\ell^{1}(\mathbb{N})$ is complete. Let $a^{n}=\left(a_{j}^{n}\right)_{j=1}^{\infty}$ be a Cauchy sequence; that is, for given $\varepsilon>0$ we can find an $N_{\varepsilon}$ such that $\left\|a^{m}-a^{n}\right\|_{1} \leq \varepsilon$ for $m, n \geq N_{\varepsilon}$. This implies in particular $\left|a_{j}^{m}-a_{j}^{n}\right| \leq \varepsilon$ for any fixed $j$. Thus $a_{j}^{n}$ is a Cauchy sequence for fixed $j$ and by completeness of $\mathbb{C}$ has a limit: $\lim _{n \rightarrow \infty} a_{j}^{n}=a_{j}$. Now consider

$$
\begin{equation*}
\sum_{j=1}^{k}\left|a_{j}^{m}-a_{j}^{n}\right| \leq \varepsilon \tag{0.23}
\end{equation*}
$$

and take $m \rightarrow \infty$ :

$$
\begin{equation*}
\sum_{j=1}^{k}\left|a_{j}-a_{j}^{n}\right| \leq \varepsilon . \tag{0.24}
\end{equation*}
$$

Since this holds for any finite $k$, we even have $\left\|a-a_{n}\right\|_{1} \leq \varepsilon$. Hence $\left(a-a_{n}\right) \in$ $\ell^{1}(\mathbb{N})$ and since $a_{n} \in \ell^{1}(\mathbb{N})$, we finally conclude $a=a_{n}+\left(a-a_{n}\right) \in \ell^{1}(\mathbb{N})$. $\diamond$

Example. The space $\ell^{\infty}(\mathbb{N})$ of all bounded sequences $a=\left(a_{j}\right)_{j=1}^{\infty}$ together with the norm

$$
\begin{equation*}
\|a\|_{\infty}=\sup _{j \in \mathbb{N}}\left|a_{j}\right| \tag{0.25}
\end{equation*}
$$

is a Banach space (Problem 0.10).
Now what about convergence in the space $C(I)$ ? A sequence of functions $f_{n}(x)$ converges to $f$ if and only if

$$
\begin{equation*}
\lim _{n \rightarrow \infty}\left\|f-f_{n}\right\|=\lim _{n \rightarrow \infty} \sup _{x \in I}\left|f_{n}(x)-f(x)\right|=0 \tag{0.26}
\end{equation*}
$$

That is, in the language of real analysis, $f_{n}$ converges uniformly to $f$. Now let us look at the case where $f_{n}$ is only a Cauchy sequence. Then $f_{n}(x)$ is clearly a Cauchy sequence of real numbers for any fixed $x \in I$. In particular, by completeness of $\mathbb{C}$, there is a limit $f(x)$ for each $x$. Thus we get a limiting function $f(x)$. Moreover, letting $m \rightarrow \infty$ in

$$
\begin{equation*}
\left|f_{m}(x)-f_{n}(x)\right| \leq \varepsilon \quad \forall m, n>N_{\varepsilon}, x \in I, \tag{0.27}
\end{equation*}
$$

we see

$$
\begin{equation*}
\left|f(x)-f_{n}(x)\right| \leq \varepsilon \quad \forall n>N_{\varepsilon}, x \in I ; \tag{0.28}
\end{equation*}
$$

that is, $f_{n}(x)$ converges uniformly to $f(x)$. However, up to this point we do not know whether it is in our vector space $C(I)$ or not, that is, whether it is continuous or not. Fortunately, there is a well-known result from real analysis which tells us that the uniform limit of continuous functions is again continuous. Hence $f(x) \in C(I)$ and thus every Cauchy sequence in $C(I)$ converges. Or, in other words

Theorem 0.14. $C(I)$ with the maximum norm is a Banach space.
Next we want to know if there is a countable basis for $C(I)$. We will call a set of vectors $\left\{u_{n}\right\} \subset X$ linearly independent if every finite subset is and we will call a countable set of linearly independent vectors $\left\{u_{n}\right\}_{n=1}^{N} \subset X$ a Schauder basis if every element $f \in X$ can be uniquely written as a countable linear combination of the basis elements:

$$
\begin{equation*}
f=\sum_{n=1}^{N} c_{n} u_{n}, \quad c_{n}=c_{n}(f) \in \mathbb{C} \tag{0.29}
\end{equation*}
$$

where the sum has to be understood as a limit if $N=\infty$. In this case the span $\operatorname{span}\left\{u_{n}\right\}$ (the set of all finite linear combinations) of $\left\{u_{n}\right\}$ is dense in $X$. A set whose span is dense is called total and if we have a countable total set, we also have a countable dense set (consider only linear combinations with rational coefficients - show this). A normed linear space containing a countable dense set is called separable.
Example. The Banach space $\ell^{1}(\mathbb{N})$ is separable. In fact, the set of vectors $\delta^{n}$, with $\delta_{n}^{n}=1$ and $\delta_{m}^{n}=0, n \neq m$, is total: Let $a=\left(a_{j}\right)_{j=1}^{\infty} \in \ell^{1}(\mathbb{N})$ be given and set $a^{n}=\sum_{j=1}^{n} a_{j} \delta^{j}$. Then

$$
\begin{equation*}
\left\|a-a^{n}\right\|_{1}=\sum_{j=n+1}^{\infty}\left|a_{j}\right| \rightarrow 0 \tag{0.30}
\end{equation*}
$$

since $a_{j}^{n}=a_{j}$ for $1 \leq j \leq n$ and $a_{j}^{n}=0$ for $j>n$.
Luckily this is also the case for $C(I)$ :
Theorem 0.15 (Weierstraß). Let I be a compact interval. Then the set of polynomials is dense in $C(I)$.

Proof. Let $f(x) \in C(I)$ be given. By considering $f(x)-f(a)+(f(b)-$ $f(a))(x-b)$ it is no loss to assume that $f$ vanishes at the boundary points. Moreover, without restriction we only consider $I=\left[\frac{-1}{2}, \frac{1}{2}\right]$ (why?).

Now the claim follows from the lemma below using

$$
u_{n}(x)=\frac{1}{I_{n}}\left(1-x^{2}\right)^{n},
$$

where

$$
\begin{aligned}
I_{n} & =\int_{-1}^{1}\left(1-x^{2}\right)^{n} d x=\frac{n}{n+1} \int_{-1}^{1}(1-x)^{n-1}(1+x)^{n+1} d x \\
& =\cdots=\frac{n!}{(n+1) \cdots(2 n+1)} 2^{2 n+1}=\frac{n!}{\frac{1}{2}\left(\frac{1}{2}+1\right) \cdots\left(\frac{1}{2}+n\right)} \\
& =\sqrt{\pi} \frac{\Gamma(1+n)}{\Gamma\left(\frac{3}{2}+n\right)}=\sqrt{\frac{\pi}{n}}\left(1+O\left(\frac{1}{n}\right)\right) .
\end{aligned}
$$

In the last step we have used $\Gamma\left(\frac{1}{2}\right)=\sqrt{\pi}[\mathbf{1},(6.1 .8)]$ and the asymptotics follow from Stirling's formula $[\mathbf{1},(6.1 .37)]$.

Lemma 0.16 (Smoothing). Let $u_{n}(x)$ be a sequence of nonnegative continuous functions on $[-1,1]$ such that

$$
\begin{equation*}
\int_{|x| \leq 1} u_{n}(x) d x=1 \quad \text { and } \quad \int_{\delta \leq|x| \leq 1} u_{n}(x) d x \rightarrow 0, \quad \delta>0 . \tag{0.31}
\end{equation*}
$$

(In other words, $u_{n}$ has mass one and concentrates near $x=0$ as $n \rightarrow \infty$.)
Then for every $f \in C\left[-\frac{1}{2}, \frac{1}{2}\right]$ which vanishes at the endpoints, $f\left(-\frac{1}{2}\right)=$ $f\left(\frac{1}{2}\right)=0$, we have that

$$
\begin{equation*}
f_{n}(x)=\int_{-1 / 2}^{1 / 2} u_{n}(x-y) f(y) d y \tag{0.32}
\end{equation*}
$$

converges uniformly to $f(x)$.
Proof. Since $f$ is uniformly continuous, for given $\varepsilon$ we can find a $\delta$ (independent of $x$ ) such that $|f(x)-f(y)| \leq \varepsilon$ whenever $|x-y| \leq \delta$. Moreover, we can choose $n$ such that $\int_{\delta \leq|y| \leq 1} u_{n}(y) d y \leq \varepsilon$. Now abbreviate $M=\max \{1,|f|\}$ and note

$$
\left|f(x)-\int_{-1 / 2}^{1 / 2} u_{n}(x-y) f(x) d y\right|=|f(x)|\left|1-\int_{-1 / 2}^{1 / 2} u_{n}(x-y) d y\right| \leq M \varepsilon
$$

In fact, either the distance of $x$ to one of the boundary points $\pm \frac{1}{2}$ is smaller than $\delta$ and hence $|f(x)| \leq \varepsilon$ or otherwise the difference between one and the integral is smaller than $\varepsilon$.

Using this, we have

$$
\begin{align*}
\left|f_{n}(x)-f(x)\right| \leq & \int_{-1 / 2}^{1 / 2} u_{n}(x-y)|f(y)-f(x)| d y+M \varepsilon \\
\leq & \int_{|y| \leq 1 / 2,|x-y| \leq \delta} u_{n}(x-y)|f(y)-f(x)| d y \\
& +\int_{|y| \leq 1 / 2,|x-y| \geq \delta} u_{n}(x-y)|f(y)-f(x)| d y+M \varepsilon \\
= & \varepsilon+2 M \varepsilon+M \varepsilon=(1+3 M) \varepsilon, \tag{0.33}
\end{align*}
$$

which proves the claim.
Note that $f_{n}$ will be as smooth as $u_{n}$, hence the title smoothing lemma. The same idea is used to approximate noncontinuous functions by smooth ones (of course the convergence will no longer be uniform in this case).

Corollary 0.17. $C(I)$ is separable.
However, $\ell^{\infty}(\mathbb{N})$ is not separable (Problem 0.11)!
Problem 0.7. Show that $|\|f\|-\|g\|| \leq\|f-g\|$.
Problem 0.8. Let $X$ be a Banach space. Show that the norm, vector addition, and multiplication by scalars are continuous. That is, if $f_{n} \rightarrow f$, $g_{n} \rightarrow g$, and $\alpha_{n} \rightarrow \alpha$, then $\left\|f_{n}\right\| \rightarrow\|f\|, f_{n}+g_{n} \rightarrow f+g$, and $\alpha_{n} g_{n} \rightarrow \alpha g$.

Problem 0.9. Let $X$ be a Banach space. Show that $\sum_{j=1}^{\infty}\left\|f_{j}\right\|<\infty$ implies that

$$
\sum_{j=1}^{\infty} f_{j}=\lim _{n \rightarrow \infty} \sum_{j=1}^{n} f_{j}
$$

exists. The series is called absolutely convergent in this case.
Problem 0.10. Show that $\ell^{\infty}(\mathbb{N})$ is a Banach space.
Problem 0.11. Show that $\ell^{\infty}(\mathbb{N})$ is not separable. (Hint: Consider sequences which take only the value one and zero. How many are there? What is the distance between two such sequences?)

### 0.3. The geometry of Hilbert spaces

So it looks like $C(I)$ has all the properties we want. However, there is still one thing missing: How should we define orthogonality in $C(I)$ ? In Euclidean space, two vectors are called orthogonal if their scalar product vanishes, so we would need a scalar product:

Suppose $\mathfrak{H}$ is a vector space. A map $\langle., .\rangle:. \mathfrak{H} \times \mathfrak{H} \rightarrow \mathbb{C}$ is called a sesquilinear form if it is conjugate linear in the first argument and linear in the second; that is,

$$
\begin{align*}
& \left\langle\alpha_{1} f_{1}+\alpha_{2} f_{2}, g\right\rangle=\alpha_{1}^{*}\left\langle f_{1}, g\right\rangle+\alpha_{2}^{*}\left\langle f_{2}, g\right\rangle, \quad \alpha_{1}, \alpha_{2} \in \mathbb{C},, ~  \tag{0.34}\\
& \left\langle f, \alpha_{1} g_{1}+\alpha_{2} g_{2}\right\rangle
\end{align*}=\alpha_{1}\left\langle f, g_{1}\right\rangle+\alpha_{2}\left\langle f, g_{2}\right\rangle, \quad \text {, }
$$

where ' $*$ ' denotes complex conjugation. A sesquilinear form satisfying the requirements
(i) $\langle f, f\rangle>0$ for $f \neq 0 \quad$ (positive definite),
(ii) $\langle f, g\rangle=\langle g, f\rangle^{*} \quad$ (symmetry)
is called an inner product or scalar product. Associated with every scalar product is a norm

$$
\begin{equation*}
\|f\|=\sqrt{\langle f, f\rangle} . \tag{0.35}
\end{equation*}
$$

The pair $(\mathfrak{H},\langle., .\rangle$.$) is called an inner product space. If \mathfrak{H}$ is complete, it is called a Hilbert space.
Example. Clearly $\mathbb{C}^{n}$ with the usual scalar product

$$
\begin{equation*}
\langle a, b\rangle=\sum_{j=1}^{n} a_{j}^{*} b_{j} \tag{0.36}
\end{equation*}
$$

is a (finite dimensional) Hilbert space.
Example. A somewhat more interesting example is the Hilbert space $\ell^{2}(\mathbb{N})$, that is, the set of all sequences

$$
\begin{equation*}
\left\{\left.\left(a_{j}\right)_{j=1}^{\infty}\left|\sum_{j=1}^{\infty}\right| a_{j}\right|^{2}<\infty\right\} \tag{0.37}
\end{equation*}
$$

with scalar product

$$
\begin{equation*}
\langle a, b\rangle=\sum_{j=1}^{\infty} a_{j}^{*} b_{j} . \tag{0.38}
\end{equation*}
$$

(Show that this is in fact a separable Hilbert space - Problem 0.13.) $\diamond$
Of course I still owe you a proof for the claim that $\sqrt{\langle f, f\rangle}$ is indeed a norm. Only the triangle inequality is nontrivial, which will follow from the Cauchy-Schwarz inequality below.

A vector $f \in \mathfrak{H}$ is called normalized or a unit vector if $\|f\|=1$. Two vectors $f, g \in \mathfrak{H}$ are called orthogonal or perpendicular $(f \perp g)$ if $\langle f, g\rangle=0$ and parallel if one is a multiple of the other.

If $f$ and $g$ are orthogonal, we have the Pythagorean theorem:

$$
\begin{equation*}
\|f+g\|^{2}=\|f\|^{2}+\|g\|^{2}, \quad f \perp g \tag{0.39}
\end{equation*}
$$

which is one line of computation.

Suppose $u$ is a unit vector. Then the projection of $f$ in the direction of $u$ is given by

$$
\begin{equation*}
f_{\|}=\langle u, f\rangle u \tag{0.40}
\end{equation*}
$$

and $f_{\perp}$ defined via

$$
\begin{equation*}
f_{\perp}=f-\langle u, f\rangle u \tag{0.41}
\end{equation*}
$$

is perpendicular to $u$ since $\left\langle u, f_{\perp}\right\rangle=\langle u, f-\langle u, f\rangle u\rangle=\langle u, f\rangle-\langle u, f\rangle\langle u, u\rangle=$ 0 .

Taking any other vector parallel to $u$, it is easy to see

$$
\begin{equation*}
\|f-\alpha u\|^{2}=\left\|f_{\perp}+\left(f_{\|}-\alpha u\right)\right\|^{2}=\left\|f_{\perp}\right\|^{2}+|\langle u, f\rangle-\alpha|^{2} \tag{0.42}
\end{equation*}
$$

and hence $f_{\|}=\langle u, f\rangle u$ is the unique vector parallel to $u$ which is closest to $f$.

As a first consequence we obtain the Cauchy-Schwarz-Bunjakowski inequality:

Theorem 0.18 (Cauchy-Schwarz-Bunjakowski). Let $\mathfrak{H}_{0}$ be an inner product space. Then for every $f, g \in \mathfrak{H}_{0}$ we have

$$
\begin{equation*}
|\langle f, g\rangle| \leq\|f\|\|g\| \tag{0.43}
\end{equation*}
$$

with equality if and only if $f$ and $g$ are parallel.
Proof. It suffices to prove the case $\|g\|=1$. But then the claim follows from $\|f\|^{2}=|\langle g, f\rangle|^{2}+\left\|f_{\perp}\right\|^{2}$.

Note that the Cauchy-Schwarz inequality entails that the scalar product is continuous in both variables; that is, if $f_{n} \rightarrow f$ and $g_{n} \rightarrow g$, we have $\left\langle f_{n}, g_{n}\right\rangle \rightarrow\langle f, g\rangle$.

As another consequence we infer that the map $\|$.$\| is indeed a norm. In$ fact,

$$
\begin{equation*}
\|f+g\|^{2}=\|f\|^{2}+\langle f, g\rangle+\langle g, f\rangle+\|g\|^{2} \leq(\|f\|+\|g\|)^{2} . \tag{0.44}
\end{equation*}
$$

But let us return to $C(I)$. Can we find a scalar product which has the maximum norm as associated norm? Unfortunately the answer is no! The reason is that the maximum norm does not satisfy the parallelogram law (Problem 0.17).

Theorem 0.19 (Jordan-von Neumann). A norm is associated with a scalar product if and only if the parallelogram law

$$
\begin{equation*}
\|f+g\|^{2}+\|f-g\|^{2}=2\|f\|^{2}+2\|g\|^{2} \tag{0.45}
\end{equation*}
$$

holds.
In this case the scalar product can be recovered from its norm by virtue of the polarization identity

$$
\begin{equation*}
\langle f, g\rangle=\frac{1}{4}\left(\|f+g\|^{2}-\|f-g\|^{2}+\mathrm{i}\|f-\mathrm{i} g\|^{2}-\mathrm{i}\|f+\mathrm{i} g\|^{2}\right) . \tag{0.46}
\end{equation*}
$$

Proof. If an inner product space is given, verification of the parallelogram law and the polarization identity is straightforward (Problem 0.14).

To show the converse, we define

$$
s(f, g)=\frac{1}{4}\left(\|f+g\|^{2}-\|f-g\|^{2}+\mathrm{i}\|f-\mathrm{i} g\|^{2}-\mathrm{i}\|f+\mathrm{i} g\|^{2}\right) .
$$

Then $s(f, f)=\|f\|^{2}$ and $s(f, g)=s(g, f)^{*}$ are straightforward to check. Moreover, another straightforward computation using the parallelogram law shows

$$
s(f, g)+s(f, h)=2 s\left(f, \frac{g+h}{2}\right) .
$$

Now choosing $h=0$ (and using $s(f, 0)=0$ ) shows $s(f, g)=2 s\left(f, \frac{g}{2}\right)$ and thus $s(f, g)+s(f, h)=s(f, g+h)$. Furthermore, by induction we infer $\frac{m}{2^{n}} s(f, g)=s\left(f, \frac{m}{2^{n}} g\right)$; that is, $\alpha s(f, g)=s(f, \alpha g)$ for every positive rational $\alpha$. By continuity (check this!) this holds for all $\alpha>0$ and $s(f,-g)=$ $-s(f, g)$, respectively, $s(f, \mathrm{i} g)=\mathrm{i} s(f, g)$, finishes the proof.

Note that the parallelogram law and the polarization identity even hold for sesquilinear forms (Problem 0.14).

But how do we define a scalar product on $C(I)$ ? One possibility is

$$
\begin{equation*}
\langle f, g\rangle=\int_{a}^{b} f^{*}(x) g(x) d x \tag{0.47}
\end{equation*}
$$

The corresponding inner product space is denoted by $\mathcal{L}_{\text {cont }}^{2}(I)$. Note that we have

$$
\begin{equation*}
\|f\| \leq \sqrt{|b-a|}\|f\|_{\infty} \tag{0.48}
\end{equation*}
$$

and hence the maximum norm is stronger than the $\mathcal{L}_{\text {cont }}^{2}$ norm.
Suppose we have two norms $\|\cdot\|_{1}$ and $\|\cdot\|_{2}$ on a space $X$. Then $\|\cdot\|_{2}$ is said to be stronger than $\|\cdot\|_{1}$ if there is a constant $m>0$ such that

$$
\begin{equation*}
\|f\|_{1} \leq m\|f\|_{2} \tag{0.49}
\end{equation*}
$$

It is straightforward to check the following.

Lemma 0.20. If $\|\cdot\|_{2}$ is stronger than $\|\cdot\|_{1}$, then any $\|.\|_{2}$ Cauchy sequence is also $a\|\cdot\|_{1}$ Cauchy sequence.

Hence if a function $F: X \rightarrow Y$ is continuous in $\left(X,\|\cdot\|_{1}\right)$, it is also continuous in $\left(X,\|\cdot\|_{2}\right)$ and if a set is dense in $\left(X,\|\cdot\|_{2}\right)$, it is also dense in $\left(X,\|\cdot\|_{1}\right)$.

In particular, $\mathcal{L}_{\text {cont }}^{2}$ is separable. But is it also complete? Unfortunately the answer is no:
Example. Take $I=[0,2]$ and define

$$
f_{n}(x)= \begin{cases}0, & 0 \leq x \leq 1-\frac{1}{n}  \tag{0.50}\\ 1+n(x-1), & 1-\frac{1}{n} \leq x \leq 1 \\ 1, & 1 \leq x \leq 2\end{cases}
$$

Then $f_{n}(x)$ is a Cauchy sequence in $\mathcal{L}_{\text {cont }}^{2}$, but there is no limit in $\mathcal{L}_{\text {cont }}^{2}$ ! Clearly the limit should be the step function which is 0 for $0 \leq x<1$ and 1 for $1 \leq x \leq 2$, but this step function is discontinuous (Problem 0.18)!

This shows that in infinite dimensional spaces different norms will give rise to different convergent sequences! In fact, the key to solving problems in infinite dimensional spaces is often finding the right norm! This is something which cannot happen in the finite dimensional case.

Theorem 0.21. If $X$ is a finite dimensional space, then all norms are equivalent. That is, for any two given norms $\|\cdot\|_{1}$ and $\|\cdot\|_{2}$, there are constants $m_{1}$ and $m_{2}$ such that

$$
\begin{equation*}
\frac{1}{m_{2}}\|f\|_{1} \leq\|f\|_{2} \leq m_{1}\|f\|_{1} \tag{0.51}
\end{equation*}
$$

Proof. Clearly we can choose a basis $u_{j}, 1 \leq j \leq n$, and assume that $\|.\|_{2}$ is the usual Euclidean norm, $\left\|\sum_{j} \alpha_{j} u_{j}\right\|_{2}^{2}=\sum_{j}\left|\alpha_{j}\right|^{2}$. Let $f=\sum_{j} \alpha_{j} u_{j}$. Then by the triangle and Cauchy-Schwartz inequalities

$$
\|f\|_{1} \leq \sum_{j}\left|\alpha_{j}\right|\left\|u_{j}\right\|_{1} \leq \sqrt{\sum_{j}\left\|u_{j}\right\|_{1}^{2}}\|f\|_{2}
$$

and we can choose $m_{2}=\sqrt{\sum_{j}\left\|u_{j}\right\|_{1}}$.
In particular, if $f_{n}$ is convergent with respect to $\|\cdot\|_{2}$, it is also convergent with respect to $\|\cdot\|_{1}$. Thus $\|\cdot\|_{1}$ is continuous with respect to $\|\cdot\|_{2}$ and attains its minimum $m>0$ on the unit sphere (which is compact by the Heine-Borel theorem). Now choose $m_{1}=1 / \mathrm{m}$.

Problem 0.12. Show that the norm in a Hilbert space satisfies $\|f+g\|=$ $\|f\|+\|g\|$ if and only if $f=\alpha g, \alpha \geq 0$, or $g=0$.

Problem 0.13. Show that $\ell^{2}(\mathbb{N})$ is a separable Hilbert space.
Problem 0.14. Suppose $\mathfrak{Q}$ is a vector space. Let $s(f, g)$ be a sesquilinear form on $\mathfrak{Q}$ and $q(f)=s(f, f)$ the associated quadratic form. Prove the parallelogram law

$$
\begin{equation*}
q(f+g)+q(f-g)=2 q(f)+2 q(g) \tag{0.52}
\end{equation*}
$$

and the polarization identity

$$
\begin{equation*}
s(f, g)=\frac{1}{4}(q(f+g)-q(f-g)+\mathrm{i} q(f-\mathrm{i} g)-\mathrm{i} q(f+\mathrm{i} g)) . \tag{0.53}
\end{equation*}
$$

Conversely, show that any quadratic form $q(f): \mathfrak{Q} \rightarrow \mathbb{R}$ satisfying $q(\alpha f)=|\alpha|^{2} q(f)$ and the parallelogram law gives rise to a sesquilinear form via the polarization identity.

Problem 0.15. A sesquilinear form is called bounded if

$$
\|s\|=\sup _{\|f\|=\|g\|=1}|s(f, g)|
$$

is finite. Similarly, the associated quadratic form $q$ is bounded if

$$
\|q\|=\sup _{\|f\|=1}|q(f)|
$$

is finite. Show

$$
\|q\| \leq\|s\| \leq 2\|q\| .
$$

(Hint: Use the parallelogram law and the polarization identity from the previous problem.)

Problem 0.16. Suppose $\mathfrak{Q}$ is a vector space. Let $s(f, g)$ be a sesquilinear form on $\mathfrak{Q}$ and $q(f)=s(f, f)$ the associated quadratic form. Show that the Cauchy-Schwarz inequality

$$
\begin{equation*}
|s(f, g)| \leq q(f)^{1 / 2} q(g)^{1 / 2} \tag{0.54}
\end{equation*}
$$

holds if $q(f) \geq 0$.
(Hint: Consider $0 \leq q(f+\alpha g)=q(f)+2 \operatorname{Re}(\alpha s(f, g))+|\alpha|^{2} q(g)$ and choose $\alpha=t s(f, g)^{*} /|s(f, g)|$ with $t \in \mathbb{R}$.)

Problem 0.17. Show that the maximum norm (on $C[0,1]$ ) does not satisfy the parallelogram law.

Problem 0.18. Prove the claims made about $f_{n}$, defined in (0.50), in the last example.

### 0.4. Completeness

Since $\mathcal{L}_{\text {cont }}^{2}$ is not complete, how can we obtain a Hilbert space from it? Well, the answer is simple: take the completion.

If $X$ is an (incomplete) normed space, consider the set of all Cauchy sequences $\tilde{X}$. Call two Cauchy sequences equivalent if their difference converges to zero and denote by $\bar{X}$ the set of all equivalence classes. It is easy to see that $\bar{X}$ (and $\tilde{X}$ ) inherit the vector space structure from $X$. Moreover,

Lemma 0.22. If $x_{n}$ is a Cauchy sequence, then $\left\|x_{n}\right\|$ converges.
Consequently the norm of a Cauchy sequence $\left(x_{n}\right)_{n=1}^{\infty}$ can be defined by $\left\|\left(x_{n}\right)_{n=1}^{\infty}\right\|=\lim _{n \rightarrow \infty}\left\|x_{n}\right\|$ and is independent of the equivalence class (show this!). Thus $\bar{X}$ is a normed space ( $\tilde{X}$ is not! Why?).

Theorem 0.23. $\bar{X}$ is a Banach space containing $X$ as a dense subspace if we identify $x \in X$ with the equivalence class of all sequences converging to $x$.

Proof. (Outline) It remains to show that $\bar{X}$ is complete. Let $\xi_{n}=\left[\left(x_{n, j}\right)_{j=1}^{\infty}\right]$ be a Cauchy sequence in $\bar{X}$. Then it is not hard to see that $\xi=\left[\left(x_{j, j}\right)_{j=1}^{\infty}\right]$ is its limit.

Let me remark that the completion $\bar{X}$ is unique. More precisely any other complete space which contains $X$ as a dense subset is isomorphic to $\bar{X}$. This can for example be seen by showing that the identity map on $X$ has a unique extension to $\bar{X}$ (compare Theorem 0.26 below).

In particular it is no restriction to assume that a normed linear space or an inner product space is complete. However, in the important case of $\mathcal{L}_{\text {cont }}^{2}$ it is somewhat inconvenient to work with equivalence classes of Cauchy sequences and hence we will give a different characterization using the Lebesgue integral later.

### 0.5. Bounded operators

A linear map $A$ between two normed spaces $X$ and $Y$ will be called a (linear) operator

$$
\begin{equation*}
A: \mathfrak{D}(A) \subseteq X \rightarrow Y \tag{0.55}
\end{equation*}
$$

The linear subspace $\mathfrak{D}(A)$ on which $A$ is defined is called the domain of $A$ and is usually required to be dense. The kernel

$$
\begin{equation*}
\operatorname{Ker}(A)=\{f \in \mathfrak{D}(A) \mid A f=0\} \tag{0.56}
\end{equation*}
$$

and range

$$
\begin{equation*}
\operatorname{Ran}(A)=\{A f \mid f \in \mathfrak{D}(A)\}=A \mathfrak{D}(A) \tag{0.57}
\end{equation*}
$$

are defined as usual. The operator $A$ is called bounded if the operator norm

$$
\begin{equation*}
\|A\|=\sup _{\|f\|_{X}=1}\|A f\|_{Y} \tag{0.58}
\end{equation*}
$$

is finite.
The set of all bounded linear operators from $X$ to $Y$ is denoted by $\mathfrak{L}(X, Y)$. If $X=Y$, we write $\mathfrak{L}(X, X)=\mathfrak{L}(X)$.
Theorem 0.24. The space $\mathfrak{L}(X, Y)$ together with the operator norm (0.58) is a normed space. It is a Banach space if $Y$ is.

Proof. That (0.58) is indeed a norm is straightforward. If $Y$ is complete and $A_{n}$ is a Cauchy sequence of operators, then $A_{n} f$ converges to an element $g$ for every $f$. Define a new operator $A$ via $A f=g$. By continuity of the vector operations, $A$ is linear and by continuity of the norm $\|A f\|=$ $\lim _{n \rightarrow \infty}\left\|A_{n} f\right\| \leq\left(\lim _{n \rightarrow \infty}\left\|A_{n}\right\|\right)\|f\|$, it is bounded. Furthermore, given $\varepsilon>0$ there is some $N$ such that $\left\|A_{n}-A_{m}\right\| \leq \varepsilon$ for $n, m \geq N$ and thus $\left\|A_{n} f-A_{m} f\right\| \leq \varepsilon\|f\|$. Taking the limit $m \rightarrow \infty$, we see $\left\|A_{n} f-A f\right\| \leq \varepsilon\|f\|$; that is, $A_{n} \rightarrow A$.

By construction, a bounded operator is Lipschitz continuous,

$$
\begin{equation*}
\|A f\|_{Y} \leq\|A\|\|f\|_{X} \tag{0.59}
\end{equation*}
$$

and hence continuous. The converse is also true
Theorem 0.25. An operator $A$ is bounded if and only if it is continuous.
Proof. Suppose $A$ is continuous but not bounded. Then there is a sequence of unit vectors $u_{n}$ such that $\left\|A u_{n}\right\| \geq n$. Then $f_{n}=\frac{1}{n} u_{n}$ converges to 0 but $\left\|A f_{n}\right\| \geq 1$ does not converge to 0 .

Moreover, if $A$ is bounded and densely defined, it is no restriction to assume that it is defined on all of $X$.

Theorem 0.26 (B.L.T. theorem). Let $A \in \mathfrak{L}(X, Y)$ and let $Y$ be a Banach space. If $\mathfrak{D}(A)$ is dense, there is a unique (continuous) extension of $A$ to $X$ which has the same norm.

Proof. Since a bounded operator maps Cauchy sequences to Cauchy sequences, this extension can only be given by

$$
A f=\lim _{n \rightarrow \infty} A f_{n}, \quad f_{n} \in \mathfrak{D}(A), \quad f \in X
$$

To show that this definition is independent of the sequence $f_{n} \rightarrow f$, let $g_{n} \rightarrow f$ be a second sequence and observe

$$
\left\|A f_{n}-A g_{n}\right\|=\left\|A\left(f_{n}-g_{n}\right)\right\| \leq\|A\|\left\|f_{n}-g_{n}\right\| \rightarrow 0
$$

From continuity of vector addition and scalar multiplication it follows that our extension is linear. Finally, from continuity of the norm we conclude that the norm does not increase.

An operator in $\mathfrak{L}(X, \mathbb{C})$ is called a bounded linear functional and the space $X^{*}=\mathfrak{L}(X, \mathbb{C})$ is called the dual space of $X$. A sequence $f_{n}$ is said to converge weakly, $f_{n} \rightarrow f$, if $\ell\left(f_{n}\right) \rightarrow \ell(f)$ for every $\ell \in X^{*}$.

The Banach space of bounded linear operators $\mathfrak{L}(X)$ even has a multiplication given by composition. Clearly this multiplication satisfies

$$
\begin{equation*}
(A+B) C=A C+B C, \quad A(B+C)=A B+B C, \quad A, B, C \in \mathfrak{L}(X) \tag{0.60}
\end{equation*}
$$

and

$$
\begin{equation*}
(A B) C=A(B C), \quad \alpha(A B)=(\alpha A) B=A(\alpha B), \quad \alpha \in \mathbb{C} . \tag{0.61}
\end{equation*}
$$

Moreover, it is easy to see that we have

$$
\begin{equation*}
\|A B\| \leq\|A\|\|B\| . \tag{0.62}
\end{equation*}
$$

However, note that our multiplication is not commutative (unless $X$ is onedimensional). We even have an identity, the identity operator $\mathbb{I}$ satisfying $\|\mathbb{I}\|=1$.

A Banach space together with a multiplication satisfying the above requirements is called a Banach algebra. In particular, note that (0.62) ensures that multiplication is continuous (Problem 0.22).

Problem 0.19. Show that the integral operator

$$
(K f)(x)=\int_{0}^{1} K(x, y) f(y) d y
$$

where $K(x, y) \in C([0,1] \times[0,1])$, defined on $\mathfrak{D}(K)=C[0,1]$ is a bounded operator both in $X=C[0,1]$ (max norm) and $X=\mathcal{L}_{\text {cont }}^{2}(0,1)$.

Problem 0.20. Show that the differential operator $A=\frac{d}{d x}$ defined on $\mathfrak{D}(A)=C^{1}[0,1] \subset C[0,1]$ is an unbounded operator.

Problem 0.21. Show that $\|A B\| \leq\|A\|\|B\|$ for every $A, B \in \mathfrak{L}(X)$.
Problem 0.22. Show that the multiplication in a Banach algebra $X$ is continuous: $x_{n} \rightarrow x$ and $y_{n} \rightarrow y$ imply $x_{n} y_{n} \rightarrow x y$.

Problem 0.23. Let

$$
f(z)=\sum_{j=0}^{\infty} f_{j} z^{j}, \quad|z|<R,
$$

be a convergent power series with convergence radius $R>0$. Suppose $A$ is a bounded operator with $\|A\|<R$. Show that

$$
f(A)=\sum_{j=0}^{\infty} f_{j} A^{j}
$$

exists and defines a bounded linear operator (cf. Problem 0.9).

### 0.6. Lebesgue $L^{p}$ spaces

For this section some basic facts about the Lebesgue integral are required. The necessary background can be found in Appendix A. To begin with, Sections A.1, A.3, and A. 4 will be sufficient.

We fix some $\sigma$-finite measure space $(X, \Sigma, \mu)$ and denote by $\mathcal{L}^{p}(X, d \mu)$, $1 \leq p$, the set of all complex-valued measurable functions for which

$$
\begin{equation*}
\|f\|_{p}=\left(\int_{X}|f|^{p} d \mu\right)^{1 / p} \tag{0.63}
\end{equation*}
$$

is finite. First of all note that $\mathcal{L}^{p}(X, d \mu)$ is a linear space, since $|f+g|^{p} \leq$ $2^{p} \max (|f|,|g|)^{p} \leq 2^{p} \max \left(|f|^{p},|g|^{p}\right) \leq 2^{p}\left(|f|^{p}+|g|^{p}\right)$. Of course our hope is that $\mathcal{L}^{p}(X, d \mu)$ is a Banach space. However, there is a small technical problem (recall that a property is said to hold almost everywhere if the set where it fails to hold is contained in a set of measure zero):

Lemma 0.27. Let $f$ be measurable. Then

$$
\begin{equation*}
\int_{X}|f|^{p} d \mu=0 \tag{0.64}
\end{equation*}
$$

if and only if $f(x)=0$ almost everywhere with respect to $\mu$.
Proof. Observe that we have $A=\{x \mid f(x) \neq 0\}=\bigcap_{n} A_{n}$, where $A_{n}=$ $\left\{x\left||f(x)|>\frac{1}{n}\right\}\right.$. If $\int|f|^{p} d \mu=0$, we must have $\mu\left(A_{n}\right)=0$ for every $n$ and hence $\mu(A)=\lim _{n \rightarrow \infty} \mu\left(A_{n}\right)=0$. The converse is obvious.

Note that the proof also shows that if $f$ is not 0 almost everywhere, there is an $\varepsilon>0$ such that $\mu(\{x||f(x)| \geq \varepsilon\})>0$.
Example. Let $\lambda$ be the Lebesgue measure on $\mathbb{R}$. Then the characteristic function of the rationals $\chi_{\mathbb{Q}}$ is zero a.e. (with respect to $\lambda$ ).

Let $\Theta$ be the Dirac measure centered at 0 . Then $f(x)=0$ a.e. (with respect to $\Theta$ ) if and only if $f(0)=0$.

Thus $\|f\|_{p}=0$ only implies $f(x)=0$ for almost every $x$, but not for all! Hence $\|\cdot\|_{p}$ is not a norm on $\mathcal{L}^{p}(X, d \mu)$. The way out of this misery is to identify functions which are equal almost everywhere: Let

$$
\begin{equation*}
\mathcal{N}(X, d \mu)=\{f \mid f(x)=0 \mu \text {-almost everywhere }\} . \tag{0.65}
\end{equation*}
$$

Then $\mathcal{N}(X, d \mu)$ is a linear subspace of $\mathcal{L}^{p}(X, d \mu)$ and we can consider the quotient space

$$
\begin{equation*}
L^{p}(X, d \mu)=\mathcal{L}^{p}(X, d \mu) / \mathcal{N}(X, d \mu) \tag{0.66}
\end{equation*}
$$

If $d \mu$ is the Lebesgue measure on $X \subseteq \mathbb{R}^{n}$, we simply write $L^{p}(X)$. Observe that $\|f\|_{p}$ is well-defined on $L^{p}(X, d \mu)$.

Even though the elements of $L^{p}(X, d \mu)$ are, strictly speaking, equivalence classes of functions, we will still call them functions for notational convenience. However, note that for $f \in L^{p}(X, d \mu)$ the value $f(x)$ is not well-defined (unless there is a continuous representative and different continuous functions are in different equivalence classes, e.g., in the case of Lebesgue measure).

With this modification we are back in business since $L^{p}(X, d \mu)$ turns out to be a Banach space. We will show this in the following sections.

But before that let us also define $L^{\infty}(X, d \mu)$. It should be the set of bounded measurable functions $B(X)$ together with the sup norm. The only problem is that if we want to identify functions equal almost everywhere, the supremum is no longer independent of the equivalence class. The solution is the essential supremum

$$
\begin{equation*}
\|f\|_{\infty}=\inf \{C \mid \mu(\{x| | f(x) \mid>C\})=0\} . \tag{0.67}
\end{equation*}
$$

That is, $C$ is an essential bound if $|f(x)| \leq C$ almost everywhere and the essential supremum is the infimum over all essential bounds.
Example. If $\lambda$ is the Lebesgue measure, then the essential sup of $\chi_{\mathbb{Q}}$ with respect to $\lambda$ is 0 . If $\Theta$ is the Dirac measure centered at 0 , then the essential $\sup$ of $\chi_{\mathbb{Q}}$ with respect to $\Theta$ is 1 (since $\chi_{\mathbb{Q}}(0)=1$, and $x=0$ is the only point which counts for $\Theta$ ).

As before we set

$$
\begin{equation*}
L^{\infty}(X, d \mu)=B(X) / \mathcal{N}(X, d \mu) \tag{0.68}
\end{equation*}
$$

and observe that $\|f\|_{\infty}$ is independent of the equivalence class.
If you wonder where the $\infty$ comes from, have a look at Problem 0.24.
As a preparation for proving that $L^{p}$ is a Banach space, we will need Hölder's inequality, which plays a central role in the theory of $L^{p}$ spaces. In particular, it will imply Minkowski's inequality, which is just the triangle inequality for $L^{p}$.

Theorem 0.28 (Hölder's inequality). Let $p$ and $q$ be dual indices; that is,

$$
\begin{equation*}
\frac{1}{p}+\frac{1}{q}=1 \tag{0.69}
\end{equation*}
$$

with $1 \leq p \leq \infty$. If $f \in L^{p}(X, d \mu)$ and $g \in L^{q}(X, d \mu)$, then $f g \in L^{1}(X, d \mu)$ and

$$
\begin{equation*}
\|f g\|_{1} \leq\|f\|_{p}\|g\|_{q} \tag{0.70}
\end{equation*}
$$

Proof. The case $p=1, q=\infty$ (respectively $p=\infty, q=1$ ) follows directly from the properties of the integral and hence it remains to consider $1<$ $p, q<\infty$.

First of all it is no restriction to assume $\|f\|_{p}=\|g\|_{q}=1$. Then, using the elementary inequality (Problem 0.25)

$$
\begin{equation*}
a^{1 / p} b^{1 / q} \leq \frac{1}{p} a+\frac{1}{q} b, \quad a, b \geq 0 \tag{0.71}
\end{equation*}
$$

with $a=|f|^{p}$ and $b=|g|^{q}$ and integrating over $X$ gives

$$
\int_{X}|f g| d \mu \leq \frac{1}{p} \int_{X}|f|^{p} d \mu+\frac{1}{q} \int_{X}|g|^{q} d \mu=1
$$

and finishes the proof.
As a consequence we also get
Theorem 0.29 (Minkowski's inequality). Let $f, g \in L^{p}(X, d \mu)$. Then

$$
\begin{equation*}
\|f+g\|_{p} \leq\|f\|_{p}+\|g\|_{p} \tag{0.72}
\end{equation*}
$$

Proof. Since the cases $p=1, \infty$ are straightforward, we only consider $1<$ $p<\infty$. Using $|f+g|^{p} \leq|f||f+g|^{p-1}+|g||f+g|^{p-1}$, we obtain from Hölder's inequality (note $(p-1) q=p$ )

$$
\begin{aligned}
\|f+g\|_{p}^{p} & \leq\|f\|_{p}\left\|(f+g)^{p-1}\right\|_{q}+\|g\|_{p}\left\|(f+g)^{p-1}\right\|_{q} \\
& =\left(\|f\|_{p}+\|g\|_{p}\right)\|(f+g)\|_{p}^{p-1}
\end{aligned}
$$

This shows that $L^{p}(X, d \mu)$ is a normed linear space. Finally it remains to show that $L^{p}(X, d \mu)$ is complete.
Theorem 0.30. The space $L^{p}(X, d \mu)$ is a Banach space.
Proof. Suppose $f_{n}$ is a Cauchy sequence. It suffices to show that some subsequence converges (show this). Hence we can drop some terms such that

$$
\left\|f_{n+1}-f_{n}\right\|_{p} \leq \frac{1}{2^{n}}
$$

Now consider $g_{n}=f_{n}-f_{n-1}\left(\right.$ set $\left.f_{0}=0\right)$. Then

$$
G(x)=\sum_{k=1}^{\infty}\left|g_{k}(x)\right|
$$

is in $L^{p}$. This follows from

$$
\left\|\sum_{k=1}^{n}\left|g_{k}\right|\right\|_{p} \leq \sum_{k=1}^{n}\left\|g_{k}(x)\right\|_{p} \leq\left\|f_{1}\right\|_{p}+\frac{1}{2}
$$

using the monotone convergence theorem. In particular, $G(x)<\infty$ almost everywhere and the sum

$$
\sum_{n=1}^{\infty} g_{n}(x)=\lim _{n \rightarrow \infty} f_{n}(x)
$$

is absolutely convergent for those $x$. Now let $f(x)$ be this limit. Since $\left|f(x)-f_{n}(x)\right|^{p}$ converges to zero almost everywhere and $\left|f(x)-f_{n}(x)\right|^{p} \leq$ $2^{p} G(x)^{p} \in L^{1}$, dominated convergence shows $\left\|f-f_{n}\right\|_{p} \rightarrow 0$.

In particular, in the proof of the last theorem we have seen:
Corollary 0.31. If $\left\|f_{n}-f\right\|_{p} \rightarrow 0$, then there is a subsequence which converges pointwise almost everywhere.

Note that the statement is not true in general without passing to a subsequence (Problem 0.28).

Using Hölder's inequality, we can also identify a class of bounded operators in $L^{p}$.

Lemma 0.32 (Schur criterion). Consider $L^{p}(X, d \mu)$ and $L^{q}(X, d \nu)$ with $\frac{1}{p}+\frac{1}{q}=1$. Suppose that $K(x, y)$ is measurable and there are measurable functions $K_{1}(x, y), K_{2}(x, y)$ such that $|K(x, y)| \leq K_{1}(x, y) K_{2}(x, y)$ and

$$
\begin{equation*}
\left\|K_{1}(x, .)\right\|_{q} \leq C_{1}, \quad\left\|K_{2}(., y)\right\|_{p} \leq C_{2} \tag{0.73}
\end{equation*}
$$

for $\mu$-almost every $x$, respectively, for $\nu$-almost every $y$. Then the operator $K: L^{p}(X, d \mu) \rightarrow L^{p}(X, d \mu)$ defined by

$$
\begin{equation*}
(K f)(x)=\int_{Y} K(x, y) f(y) d \nu(y) \tag{0.74}
\end{equation*}
$$

for $\mu$-almost every $x$ is bounded with $\|K\| \leq C_{1} C_{2}$.
Proof. Choose $f \in L^{p}(X, d \mu)$. By Fubini's theorem $\int_{Y}|K(x, y) f(y)| d \nu(y)$ is measurable and by Hölder's inequality we have

$$
\begin{aligned}
\int_{Y} \mid & K(x, y) f(y)\left|d \nu(y) \leq \int_{Y} K_{1}(x, y) K_{2}(x, y)\right| f(y) \mid d \nu(y) \\
& \leq\left(\int_{Y} K_{1}(x, y)^{q} d \nu(y)\right)^{1 / q}\left(\int_{Y}\left|K_{2}(x, y) f(y)\right|^{p} d \nu(y)\right)^{1 / p} \\
& \leq C_{1}\left(\int_{Y}\left|K_{2}(x, y) f(y)\right|^{p} d \nu(y)\right)^{1 / p}
\end{aligned}
$$

(if $K_{2}(x,) f.(.) \notin L^{p}(X, d \nu)$, the inequality is trivially true). Now take this inequality to the $p^{\prime}$ 'th power and integrate with respect to $x$ using Fubini

$$
\begin{gathered}
\int_{X}\left(\int_{Y}|K(x, y) f(y)| d \nu(y)\right)^{p} d \mu(x) \leq C_{1}^{p} \int_{X} \int_{Y}\left|K_{2}(x, y) f(y)\right|^{p} d \nu(y) d \mu(x) \\
=C_{1}^{p} \int_{Y} \int_{X}\left|K_{2}(x, y) f(y)\right|^{p} d \mu(x) d \mu(y) \leq C_{1}^{p} C_{2}^{p}\|f\|_{p}^{p}
\end{gathered}
$$

Hence $\int_{Y}|K(x, y) f(y)| d \nu(y) \in L^{p}(X, d \mu)$ and in particular it is finite for $\mu$-almost every $x$. Thus $K(x,) f.($.$) is \nu$ integrable for $\mu$-almost every $x$ and $\int_{Y} K(x, y) f(y) d \nu(y)$ is measurable.

It even turns out that $L^{p}$ is separable.
Lemma 0.33. Suppose $X$ is a second countable topological space (i.e., it has a countable basis) and $\mu$ is a regular Borel measure. Then $L^{p}(X, d \mu)$, $1 \leq p<\infty$, is separable.

Proof. The set of all characteristic functions $\chi_{A}(x)$ with $A \in \Sigma$ and $\mu(A)<$ $\infty$ is total by construction of the integral. Now our strategy is as follows: Using outer regularity, we can restrict $A$ to open sets and using the existence of a countable base, we can restrict $A$ to open sets from this base.

Fix $A$. By outer regularity, there is a decreasing sequence of open sets $O_{n}$ such that $\mu\left(O_{n}\right) \rightarrow \mu(A)$. Since $\mu(A)<\infty$, it is no restriction to assume $\mu\left(O_{n}\right)<\infty$, and thus $\mu\left(O_{n} \backslash A\right)=\mu\left(O_{n}\right)-\mu(A) \rightarrow 0$. Now dominated convergence implies $\left\|\chi_{A}-\chi_{O_{n}}\right\|_{p} \rightarrow 0$. Thus the set of all characteristic functions $\chi_{O}(x)$ with $O$ open and $\mu(O)<\infty$ is total. Finally let $\mathcal{B}$ be a countable basis for the topology. Then, every open set $O$ can be written as $O=\bigcup_{j=1}^{\infty} \tilde{O}_{j}$ with $\tilde{O}_{j} \in \mathcal{B}$. Moreover, by considering the set of all finite unions of elements from $\mathcal{B}$, it is no restriction to assume $\bigcup_{j=1}^{n} \tilde{O}_{j} \in \mathcal{B}$. Hence there is an increasing sequence $\tilde{O}_{n} \nearrow O$ with $\tilde{O}_{n} \in \mathcal{B}$. By monotone convergence, $\left\|\chi_{O}-\chi_{\tilde{O}_{n}}\right\|_{p} \rightarrow 0$ and hence the set of all characteristic functions $\chi_{\tilde{O}}$ with $\tilde{O} \in \mathcal{B}$ is total.

To finish this chapter, let us show that continuous functions are dense in $L^{p}$.

Theorem 0.34. Let $X$ be a locally compact metric space and let $\mu$ be a $\sigma$-finite regular Borel measure. Then the set $C_{c}(X)$ of continuous functions with compact support is dense in $L^{p}(X, d \mu), 1 \leq p<\infty$.

Proof. As in the previous proof the set of all characteristic functions $\chi_{K}(x)$ with $K$ compact is total (using inner regularity). Hence it suffices to show that $\chi_{K}(x)$ can be approximated by continuous functions. By outer regularity there is an open set $O \supset K$ such that $\mu(O \backslash K) \leq \varepsilon$. By Urysohn's
lemma (Lemma 0.12) there is a continuous function $f_{\varepsilon}$ which is 1 on $K$ and 0 outside $O$. Since

$$
\int_{X}\left|\chi_{K}-f_{\varepsilon}\right|^{p} d \mu=\int_{O \backslash K}\left|f_{\varepsilon}\right|^{p} d \mu \leq \mu(O \backslash K) \leq \varepsilon,
$$

we have $\left\|f_{\varepsilon}-\chi_{K}\right\| \rightarrow 0$ and we are done.
If $X$ is some subset of $\mathbb{R}^{n}$, we can do even better. A nonnegative function $u \in C_{c}^{\infty}\left(\mathbb{R}^{n}\right)$ is called a mollifier if

$$
\begin{equation*}
\int_{\mathbb{R}^{n}} u(x) d x=1 . \tag{0.75}
\end{equation*}
$$

The standard mollifier is $u(x)=\exp \left(\frac{1}{|x|^{2}-1}\right)$ for $|x|<1$ and $u(x)=0$ otherwise.

If we scale a mollifier according to $u_{k}(x)=k^{n} u(k x)$ such that its mass is preserved $\left(\left\|u_{k}\right\|_{1}=1\right)$ and it concentrates more and more around the origin,

we have the following result (Problem 0.29):
Lemma 0.35. Let $u$ be a mollifier in $\mathbb{R}^{n}$ and set $u_{k}(x)=k^{n} u(k x)$. Then for any (uniformly) continuous function $f: \mathbb{R}^{n} \rightarrow \mathbb{C}$ we have that

$$
\begin{equation*}
f_{k}(x)=\int_{\mathbb{R}^{n}} u_{k}(x-y) f(y) d y \tag{0.76}
\end{equation*}
$$

is in $C^{\infty}\left(\mathbb{R}^{n}\right)$ and converges to $f$ (uniformly).
Now we are ready to prove
Theorem 0.36. If $X \subseteq \mathbb{R}^{n}$ and $\mu$ is a regular Borel measure, then the set $C_{c}^{\infty}(X)$ of all smooth functions with compact support is dense in $L^{p}(X, d \mu)$, $1 \leq p<\infty$.

Proof. By our previous result it suffices to show that any continuous function $f(x)$ with compact support can be approximated by smooth ones. By setting $f(x)=0$ for $x \notin X$, it is no restriction to assume $X=\mathbb{R}^{n}$. Now choose a mollifier $u$ and observe that $f_{k}$ has compact support (since $f$
has). Moreover, since $f$ has compact support, it is uniformly continuous and $f_{k} \rightarrow f$ uniformly. But this implies $f_{k} \rightarrow f$ in $L^{p}$.

We say that $f \in L_{l o c}^{p}(X)$ if $f \in L^{p}(K)$ for any compact subset $K \subset X$.
Lemma 0.37. Suppose $f \in L_{\text {loc }}^{1}\left(\mathbb{R}^{n}\right)$. Then

$$
\begin{equation*}
\int_{\mathbb{R}^{n}} \varphi(x) f(x) d x=0, \quad \forall \varphi \in C_{c}^{\infty}\left(\mathbb{R}^{n}\right) \tag{0.77}
\end{equation*}
$$

if and only if $f(x)=0$ (a.e.).
Proof. First of all we claim that for any bounded function $g$ with compact support $K$, there is a sequence of functions $\varphi_{n} \in C_{c}^{\infty}\left(\mathbb{R}^{n}\right)$ with support in $K$ which converges pointwise to $g$ such that $\left\|\varphi_{n}\right\|_{\infty} \leq\|g\|_{\infty}$.

To see this, take a sequence of continuous functions $\varphi_{n}$ with support in $K$ which converges to $g$ in $L^{1}$. To make sure that $\left\|\varphi_{n}\right\|_{\infty} \leq\|g\|_{\infty}$, just set it equal to $\|g\|_{\infty}$ whenever $\varphi_{n}>\|g\|_{\infty}$ and equal to $-\|g\|_{\infty}$ whenever $\varphi_{n}<\|g\|_{\infty}$ (show that the resulting sequence still converges). Finally use (0.76) to make $\varphi_{n}$ smooth (note that this operation does not change the range) and extract a pointwise convergent subsequence.

Now let $K$ be some compact set and choose $g=\operatorname{sign}(f) \chi_{K}$. Then

$$
\int_{K}|f| d x=\int_{K} f \operatorname{sign}(f) d x=\lim _{n \rightarrow \infty} \int f \chi_{n} d x=0
$$

which shows $f=0$ for a.e. $x \in K$. Since $K$ is arbitrary, we are done.
Problem 0.24. Suppose $\mu(X)<\infty$. Show that

$$
\lim _{p \rightarrow \infty}\|f\|_{p}=\|f\|_{\infty}
$$

for any bounded measurable function.
Problem 0.25. Prove (0.71). (Hint: Take logarithms on both sides.)
Problem 0.26. Show the following generalization of Hölder's inequality:

$$
\begin{equation*}
\|f g\|_{r} \leq\|f\|_{p}\|g\|_{q}, \tag{0.78}
\end{equation*}
$$

where $\frac{1}{p}+\frac{1}{q}=\frac{1}{r}$.
Problem 0.27 (Lyapunov inequality). Let $0<\theta<1$. Show that if $f \in$ $L^{p_{1}} \cap L^{p_{2}}$, then $f \in L^{p}$ and

$$
\begin{equation*}
\|f\|_{p} \leq\|f\|_{p_{1}}^{\theta}\|f\|_{p_{2}}^{1-\theta} \tag{0.79}
\end{equation*}
$$

where $\frac{1}{p}=\frac{\theta}{p_{1}}+\frac{1-\theta}{p_{2}}$.

Problem 0.28. Find a sequence $f_{n}$ which converges to 0 in $L^{p}([0,1], d x)$ but for which $f_{n}(x) \rightarrow 0$ for a.e. $x \in[0,1]$ does not hold. (Hint: Every $n \in \mathbb{N}$ can be uniquely written as $n=2^{m}+k$ with $0 \leq m$ and $0 \leq k<2^{m}$. Now consider the characteristic functions of the intervals $I_{m, k}=\left[k 2^{-m},(k+1) 2^{-m}\right]$.)

Problem 0.29. Prove Lemma 0.35. (Hint: To show that $f_{k}$ is smooth, use Problems A. 7 and A.8.)

Problem 0.30. Construct a function $f \in L^{p}(0,1)$ which has a singularity at every rational number in $[0,1]$. (Hint: Start with the function $f_{0}(x)=|x|^{-\alpha}$ which has a single pole at 0 . Then $f_{j}(x)=f_{0}\left(x-x_{j}\right)$ has a pole at $x_{j}$.)

### 0.7. Appendix: The uniform boundedness principle

Recall that the interior of a set is the largest open subset (that is, the union of all open subsets). A set is called nowhere dense if its closure has empty interior. The key to several important theorems about Banach spaces is the observation that a Banach space cannot be the countable union of nowhere dense sets.

Theorem 0.38 (Baire category theorem). Let $X$ be a complete metric space. Then $X$ cannot be the countable union of nowhere dense sets.

Proof. Suppose $X=\bigcup_{n=1}^{\infty} X_{n}$. We can assume that the sets $X_{n}$ are closed and none of them contains a ball; that is, $X \backslash X_{n}$ is open and nonempty for every $n$. We will construct a Cauchy sequence $x_{n}$ which stays away from all $X_{n}$.

Since $X \backslash X_{1}$ is open and nonempty, there is a closed ball $B_{r_{1}}\left(x_{1}\right) \subseteq$ $X \backslash X_{1}$. Reducing $r_{1}$ a little, we can even assume $\overline{B_{r_{1}}\left(x_{1}\right)} \subseteq X \backslash X_{1}$. Moreover, since $X_{2}$ cannot contain $B_{r_{1}}\left(x_{1}\right)$, there is some $x_{2} \in B_{r_{1}}\left(x_{1}\right)$ that is not in $X_{2}$. Since $B_{r_{1}}\left(x_{1}\right) \cap\left(X \backslash X_{2}\right)$ is open, there is a closed ball $\overline{B_{r_{2}}\left(x_{2}\right)} \subseteq$ $B_{r_{1}}\left(x_{1}\right) \cap\left(X \backslash X_{2}\right)$. Proceeding by induction, we obtain a sequence of balls such that

$$
\overline{B_{r_{n}}\left(x_{n}\right)} \subseteq B_{r_{n-1}}\left(x_{n-1}\right) \cap\left(X \backslash X_{n}\right) .
$$

Now observe that in every step we can choose $r_{n}$ as small as we please; hence without loss of generality $r_{n} \rightarrow 0$. Since by construction $x_{n} \in \overline{B_{r_{N}}\left(x_{N}\right)}$ for $n \geq N$, we conclude that $x_{n}$ is Cauchy and converges to some point $x \in X$. But $x \in \overline{B_{r_{n}}\left(x_{n}\right)} \subseteq X \backslash X_{n}$ for every $n$, contradicting our assumption that the $X_{n}$ cover $X$.
(Sets which can be written as the countable union of nowhere dense sets are said to be of first category. All other sets are second category. Hence we have the name category theorem.)

In other words, if $X_{n} \subseteq X$ is a sequence of closed subsets which cover $X$, at least one $X_{n}$ contains a ball of radius $\varepsilon>0$.

Now we come to the first important consequence, the uniform boundedness principle.

Theorem 0.39 (Banach-Steinhaus). Let $X$ be a Banach space and $Y$ some normed linear space. Let $\left\{A_{\alpha}\right\} \subseteq \mathfrak{L}(X, Y)$ be a family of bounded operators. Suppose $\left\|A_{\alpha} x\right\| \leq C(x)$ is bounded for fixed $x \in X$. Then $\left\|A_{\alpha}\right\| \leq C$ is uniformly bounded.

Proof. Let

$$
X_{n}=\left\{x \mid\left\|A_{\alpha} x\right\| \leq n \text { for all } \alpha\right\}=\bigcap_{\alpha}\left\{x \mid\left\|A_{\alpha} x\right\| \leq n\right\} .
$$

Then $\bigcup_{n} X_{n}=X$ by assumption. Moreover, by continuity of $A_{\alpha}$ and the norm, each $X_{n}$ is an intersection of closed sets and hence closed. By Baire's theorem at least one contains a ball of positive radius: $B_{\varepsilon}\left(x_{0}\right) \subset X_{n}$. Now observe

$$
\left\|A_{\alpha} y\right\| \leq\left\|A_{\alpha}\left(y+x_{0}\right)\right\|+\left\|A_{\alpha} x_{0}\right\| \leq n+\left\|A_{\alpha} x_{0}\right\|
$$

for $\|y\|<\varepsilon$. Setting $y=\varepsilon \frac{x}{\|x\|}$, we obtain

$$
\left\|A_{\alpha} x\right\| \leq \frac{n+C\left(x_{0}\right)}{\varepsilon}\|x\|
$$

for any $x$.

Part 1
Mathematical
Foundations of Quantum Mechanics

## Hilbert spaces

The phase space in classical mechanics is the Euclidean space $\mathbb{R}^{2 n}$ (for the $n$ position and $n$ momentum coordinates). In quantum mechanics the phase space is always a Hilbert space $\mathfrak{H}$. Hence the geometry of Hilbert spaces stands at the outset of our investigations.

### 1.1. Hilbert spaces

Suppose $\mathfrak{H}$ is a vector space. A map $\langle.$, ,.. $\rangle: \mathfrak{H} \times \mathfrak{H} \rightarrow \mathbb{C}$ is called a sesquilinear form if it is conjugate linear in the first argument and linear in the second. A positive definite sesquilinear form is called an inner product or scalar product. Associated with every scalar product is a norm

$$
\begin{equation*}
\|\psi\|=\sqrt{\langle\psi, \psi\rangle} . \tag{1.1}
\end{equation*}
$$

The triangle inequality follows from the Cauchy-Schwarz-Bunjakowski inequality:

$$
\begin{equation*}
|\langle\psi, \varphi\rangle| \leq\|\psi\|\|\varphi\| \tag{1.2}
\end{equation*}
$$

with equality if and only if $\psi$ and $\varphi$ are parallel.
If $\mathfrak{H}$ is complete with respect to the above norm, it is called a Hilbert space. It is no restriction to assume that $\mathfrak{H}$ is complete since one can easily replace it by its completion.
Example. The space $L^{2}(M, d \mu)$ is a Hilbert space with scalar product given by

$$
\begin{equation*}
\langle f, g\rangle=\int_{M} f(x)^{*} g(x) d \mu(x) . \tag{1.3}
\end{equation*}
$$

Similarly, the set of all square summable sequences $\ell^{2}(\mathbb{N})$ is a Hilbert space with scalar product

$$
\begin{equation*}
\langle f, g\rangle=\sum_{j \in \mathbb{N}} f_{j}^{*} g_{j} . \tag{1.4}
\end{equation*}
$$

(Note that the second example is a special case of the first one; take $M=\mathbb{R}$ and $\mu$ a sum of Dirac measures.)

A vector $\psi \in \mathfrak{H}$ is called normalized or a unit vector if $\|\psi\|=1$. Two vectors $\psi, \varphi \in \mathfrak{H}$ are called orthogonal or perpendicular $(\psi \perp \varphi)$ if $\langle\psi, \varphi\rangle=0$ and parallel if one is a multiple of the other.

If $\psi$ and $\varphi$ are orthogonal, we have the Pythagorean theorem:

$$
\begin{equation*}
\|\psi+\varphi\|^{2}=\|\psi\|^{2}+\|\varphi\|^{2}, \quad \psi \perp \varphi \tag{1.5}
\end{equation*}
$$

which is one line of computation.
Suppose $\varphi$ is a unit vector. Then the projection of $\psi$ in the direction of $\varphi$ is given by

$$
\begin{equation*}
\psi_{\|}=\langle\varphi, \psi\rangle \varphi \tag{1.6}
\end{equation*}
$$

and $\psi_{\perp}$ defined via

$$
\begin{equation*}
\psi_{\perp}=\psi-\langle\varphi, \psi\rangle \varphi \tag{1.7}
\end{equation*}
$$

is perpendicular to $\varphi$.
These results can also be generalized to more than one vector. A set of vectors $\left\{\varphi_{j}\right\}$ is called an orthonormal set (ONS) if $\left\langle\varphi_{j}, \varphi_{k}\right\rangle=0$ for $j \neq k$ and $\left\langle\varphi_{j}, \varphi_{j}\right\rangle=1$.

Lemma 1.1. Suppose $\left\{\varphi_{j}\right\}_{j=0}^{n}$ is an orthonormal set. Then every $\psi \in \mathfrak{H}$ can be written as

$$
\begin{equation*}
\psi=\psi_{\|}+\psi_{\perp}, \quad \psi_{\|}=\sum_{j=0}^{n}\left\langle\varphi_{j}, \psi\right\rangle \varphi_{j} \tag{1.8}
\end{equation*}
$$

where $\psi_{\|}$and $\psi_{\perp}$ are orthogonal. Moreover, $\left\langle\varphi_{j}, \psi_{\perp}\right\rangle=0$ for all $1 \leq j \leq n$. In particular,

$$
\begin{equation*}
\|\psi\|^{2}=\sum_{j=0}^{n}\left|\left\langle\varphi_{j}, \psi\right\rangle\right|^{2}+\left\|\psi_{\perp}\right\|^{2} \tag{1.9}
\end{equation*}
$$

Moreover, every $\hat{\psi}$ in the span of $\left\{\varphi_{j}\right\}_{j=0}^{n}$ satisfies

$$
\begin{equation*}
\|\psi-\hat{\psi}\| \geq\left\|\psi_{\perp}\right\| \tag{1.10}
\end{equation*}
$$

with equality holding if and only if $\hat{\psi}=\psi_{\|}$. In other words, $\psi_{\|}$is uniquely characterized as the vector in the span of $\left\{\varphi_{j}\right\}_{j=0}^{n}$ closest to $\psi$.

Proof. A straightforward calculation shows $\left\langle\varphi_{j}, \psi-\psi_{\|}\right\rangle=0$ and hence $\psi_{\|}$ and $\psi_{\perp}=\psi-\psi_{\|}$are orthogonal. The formula for the norm follows by applying (1.5) iteratively.

Now, fix a vector

$$
\hat{\psi}=\sum_{j=0}^{n} c_{j} \varphi_{j}
$$

in the span of $\left\{\varphi_{j}\right\}_{j=0}^{n}$. Then one computes

$$
\begin{aligned}
\|\psi-\hat{\psi}\|^{2} & =\left\|\psi_{\|}+\psi_{\perp}-\hat{\psi}\right\|^{2}=\left\|\psi_{\perp}\right\|^{2}+\left\|\psi_{\|}-\hat{\psi}\right\|^{2} \\
& =\left\|\psi_{\perp}\right\|^{2}+\sum_{j=0}^{n}\left|c_{j}-\left\langle\varphi_{j}, \psi\right\rangle\right|^{2}
\end{aligned}
$$

from which the last claim follows.
From (1.9) we obtain Bessel's inequality

$$
\begin{equation*}
\sum_{j=0}^{n}\left|\left\langle\varphi_{j}, \psi\right\rangle\right|^{2} \leq\|\psi\|^{2} \tag{1.11}
\end{equation*}
$$

with equality holding if and only if $\psi$ lies in the span of $\left\{\varphi_{j}\right\}_{j=0}^{n}$.
Recall that a scalar product can be recovered from its norm by virtue of the polarization identity

$$
\begin{equation*}
\langle\varphi, \psi\rangle=\frac{1}{4}\left(\|\varphi+\psi\|^{2}-\|\varphi-\psi\|^{2}+\mathrm{i}\|\varphi-\mathrm{i} \psi\|^{2}-\mathrm{i}\|\varphi+\mathrm{i} \psi\|^{2}\right) . \tag{1.12}
\end{equation*}
$$

A bijective linear operator $U \in \mathfrak{L}\left(\mathfrak{H}_{1}, \mathfrak{H}_{2}\right)$ is called unitary if $U$ preserves scalar products:

$$
\begin{equation*}
\langle U \varphi, U \psi\rangle_{2}=\langle\varphi, \psi\rangle_{1}, \quad \varphi, \psi \in \mathfrak{H}_{1} . \tag{1.13}
\end{equation*}
$$

By the polarization identity this is the case if and only if $U$ preserves norms: $\|U \psi\|_{2}=\|\psi\|_{1}$ for all $\psi \in \mathfrak{H}_{1}$. The two Hilbert space $\mathfrak{H}_{1}$ and $\mathfrak{H}_{2}$ are called unitarily equivalent in this case.

Problem 1.1. The operator

$$
S: \ell^{2}(\mathbb{N}) \rightarrow \ell^{2}(\mathbb{N}), \quad\left(a_{1}, a_{2}, a_{3}, \ldots\right) \mapsto\left(0, a_{1}, a_{2}, \ldots\right)
$$

satisfies $\|S a\|=\|a\|$. Is it unitary?

### 1.2. Orthonormal bases

Of course, since we cannot assume $\mathfrak{H}$ to be a finite dimensional vector space, we need to generalize Lemma 1.1 to arbitrary orthonormal sets $\left\{\varphi_{j}\right\}_{j \in J}$.

We start by assuming that $J$ is countable. Then Bessel's inequality (1.11) shows that

$$
\begin{equation*}
\sum_{j \in J}\left|\left\langle\varphi_{j}, \psi\right\rangle\right|^{2} \tag{1.14}
\end{equation*}
$$

converges absolutely. Moreover, for any finite subset $K \subset J$ we have

$$
\begin{equation*}
\left\|\sum_{j \in K}\left\langle\varphi_{j}, \psi\right\rangle \varphi_{j}\right\|^{2}=\sum_{j \in K}\left|\left\langle\varphi_{j}, \psi\right\rangle\right|^{2} \tag{1.15}
\end{equation*}
$$

by the Pythagorean theorem and thus $\sum_{j \in J}\left\langle\varphi_{j}, \psi\right\rangle \varphi_{j}$ is Cauchy if and only if $\sum_{j \in J}\left|\left\langle\varphi_{j}, \psi\right\rangle\right|^{2}$ is. Now let $J$ be arbitrary. Again, Bessel's inequality shows that for any given $\varepsilon>0$ there are at most finitely many $j$ for which $\left|\left\langle\varphi_{j}, \psi\right\rangle\right| \geq \varepsilon$. Hence there are at most countably many $j$ for which $\left|\left\langle\varphi_{j}, \psi\right\rangle\right|>$ 0 . Thus it follows that

$$
\begin{equation*}
\sum_{j \in J}\left|\left\langle\varphi_{j}, \psi\right\rangle\right|^{2} \tag{1.16}
\end{equation*}
$$

is well-defined and so is

$$
\begin{equation*}
\sum_{j \in J}\left\langle\varphi_{j}, \psi\right\rangle \varphi_{j} . \tag{1.17}
\end{equation*}
$$

In particular, by continuity of the scalar product we see that Lemma 1.1 holds for arbitrary orthonormal sets without modifications.

Theorem 1.2. Suppose $\left\{\varphi_{j}\right\}_{j \in J}$ is an orthonormal set. Then every $\psi \in \mathfrak{H}$ can be written as

$$
\begin{equation*}
\psi=\psi_{\|}+\psi_{\perp}, \quad \psi_{\|}=\sum_{j \in J}\left\langle\varphi_{j}, \psi\right\rangle \varphi_{j}, \tag{1.18}
\end{equation*}
$$

where $\psi_{\|}$and $\psi_{\perp}$ are orthogonal. Moreover, $\left\langle\varphi_{j}, \psi_{\perp}\right\rangle=0$ for all $j \in J$. In particular,

$$
\begin{equation*}
\|\psi\|^{2}=\sum_{j \in J}\left|\left\langle\varphi_{j}, \psi\right\rangle\right|^{2}+\left\|\psi_{\perp}\right\|^{2} . \tag{1.19}
\end{equation*}
$$

Moreover, every $\hat{\psi}$ in the span of $\left\{\varphi_{j}\right\}_{j \in J}$ satisfies

$$
\begin{equation*}
\|\psi-\hat{\psi}\| \geq\left\|\psi_{\perp}\right\| \tag{1.20}
\end{equation*}
$$

with equality holding if and only if $\hat{\psi}=\psi_{\|}$. In other words, $\psi_{\|}$is uniquely characterized as the vector in the span of $\left\{\varphi_{j}\right\}_{j \in J}$ closest to $\psi$.

Note that from Bessel's inequality (which of course still holds) it follows that the map $\psi \rightarrow \psi_{\|}$is continuous.

An orthonormal set which is not a proper subset of any other orthonormal set is called an orthonormal basis (ONB) due to the following result:

Theorem 1.3. For an orthonormal set $\left\{\varphi_{j}\right\}_{j \in J}$ the following conditions are equivalent:
(i) $\left\{\varphi_{j}\right\}_{j \in J}$ is a maximal orthonormal set.
(ii) For every vector $\psi \in \mathfrak{H}$ we have

$$
\begin{equation*}
\psi=\sum_{j \in J}\left\langle\varphi_{j}, \psi\right\rangle \varphi_{j} . \tag{1.21}
\end{equation*}
$$

(iii) For every vector $\psi \in \mathfrak{H}$ we have

$$
\begin{equation*}
\|\psi\|^{2}=\sum_{j \in J}\left|\left\langle\varphi_{j}, \psi\right\rangle\right|^{2} . \tag{1.22}
\end{equation*}
$$

(iv) $\left\langle\varphi_{j}, \psi\right\rangle=0$ for all $j \in J$ implies $\psi=0$.

Proof. We will use the notation from Theorem 1.2.
(i) $\Rightarrow$ (ii): If $\psi_{\perp} \neq 0$, then we can normalize $\psi_{\perp}$ to obtain a unit vector $\tilde{\psi}_{\perp}$ which is orthogonal to all vectors $\varphi_{j}$. But then $\left\{\varphi_{j}\right\}_{j \in J} \cup\left\{\tilde{\psi}_{\perp}\right\}$ would be a larger orthonormal set, contradicting the maximality of $\left\{\varphi_{j}\right\}_{j \in J}$.
(ii) $\Rightarrow$ (iii): This follows since (ii) implies $\psi_{\perp}=0$.
(iii) $\Rightarrow$ (iv): If $\left\langle\psi, \varphi_{j}\right\rangle=0$ for all $j \in J$, we conclude $\|\psi\|^{2}=0$ and hence $\psi=0$.
(iv) $\Rightarrow$ (i): If $\left\{\varphi_{j}\right\}_{j \in J}$ were not maximal, there would be a unit vector $\varphi$ such that $\left\{\varphi_{j}\right\}_{j \in J} \cup\{\varphi\}$ is a larger orthonormal set. But $\left\langle\varphi_{j}, \varphi\right\rangle=0$ for all $j \in J$ implies $\varphi=0$ by (iv), a contradiction.

Since $\psi \rightarrow \psi_{\|}$is continuous, it suffices to check conditions (ii) and (iii) on a dense set.
Example. The set of functions

$$
\begin{equation*}
\varphi_{n}(x)=\frac{1}{\sqrt{2 \pi}} \mathrm{e}^{\mathrm{i} n x}, \quad n \in \mathbb{Z} \tag{1.23}
\end{equation*}
$$

forms an orthonormal basis for $\mathfrak{H}=L^{2}(0,2 \pi)$. The corresponding orthogonal expansion is just the ordinary Fourier series (Problem 1.20).

A Hilbert space is separable if and only if there is a countable orthonormal basis. In fact, if $\mathfrak{H}$ is separable, then there exists a countable total set $\left\{\psi_{j}\right\}_{j=0}^{N}$. Here $N \in \mathbb{N}$ if $\mathfrak{H}$ is finite dimensional and $N=\infty$ otherwise. After throwing away some vectors, we can assume that $\psi_{n+1}$ cannot be expressed as a linear combinations of the vectors $\psi_{0}, \ldots, \psi_{n}$. Now we can construct an orthonormal basis as follows: We begin by normalizing $\psi_{0}$,

$$
\begin{equation*}
\varphi_{0}=\frac{\psi_{0}}{\left\|\psi_{0}\right\|} \tag{1.24}
\end{equation*}
$$

Next we take $\psi_{1}$ and remove the component parallel to $\varphi_{0}$ and normalize again:

$$
\begin{equation*}
\varphi_{1}=\frac{\psi_{1}-\left\langle\varphi_{0}, \psi_{1}\right\rangle \varphi_{0}}{\left\|\psi_{1}-\left\langle\varphi_{0}, \psi_{1}\right\rangle \varphi_{0}\right\|} \tag{1.25}
\end{equation*}
$$

Proceeding like this, we define recursively

$$
\begin{equation*}
\varphi_{n}=\frac{\psi_{n}-\sum_{j=0}^{n-1}\left\langle\varphi_{j}, \psi_{n}\right\rangle \varphi_{j}}{\left\|\psi_{n}-\sum_{j=0}^{n-1}\left\langle\varphi_{j}, \psi_{n}\right\rangle \varphi_{j}\right\|} . \tag{1.26}
\end{equation*}
$$

This procedure is known as Gram-Schmidt orthogonalization. Hence we obtain an orthonormal set $\left\{\varphi_{j}\right\}_{j=0}^{N}$ such that $\operatorname{span}\left\{\varphi_{j}\right\}_{j=0}^{n}=\operatorname{span}\left\{\psi_{j}\right\}_{j=0}^{n}$ for any finite $n$ and thus also for $N$ (if $N=\infty$ ). Since $\left\{\psi_{j}\right\}_{j=0}^{N}$ is total, so is $\left\{\varphi_{j}\right\}_{j=0}^{N}$. Now suppose there is some $\psi=\psi_{\|}+\psi_{\perp} \in \mathfrak{H}$ for which $\psi_{\perp} \neq 0$. Since $\left\{\varphi_{j}\right\}_{j=1}^{N}$ is total, we can find a $\hat{\psi}$ in its span, such that $\|\psi-\hat{\psi}\|<\left\|\psi_{\perp}\right\|$ contradicting (1.20). Hence we infer that $\left\{\varphi_{j}\right\}_{j=1}^{N}$ is an orthonormal basis.

Theorem 1.4. Every separable Hilbert space has a countable orthonormal basis.

Example. In $L^{2}(-1,1)$ we can orthogonalize the polynomial $f_{n}(x)=x^{n}$. The resulting polynomials are up to a normalization equal to the Legendre polynomials

$$
\begin{equation*}
P_{0}(x)=1, \quad P_{1}(x)=x, \quad P_{2}(x)=\frac{3 x^{2}-1}{2}, \quad \ldots \tag{1.27}
\end{equation*}
$$

(which are normalized such that $P_{n}(1)=1$ ).
If fact, if there is one countable basis, then it follows that any other basis is countable as well.

Theorem 1.5. If $\mathfrak{H}$ is separable, then every orthonormal basis is countable.
Proof. We know that there is at least one countable orthonormal basis $\left\{\varphi_{j}\right\}_{j \in J}$. Now let $\left\{\phi_{k}\right\}_{k \in K}$ be a second basis and consider the set $K_{j}=$ $\left\{k \in K \mid\left\langle\phi_{k}, \varphi_{j}\right\rangle \neq 0\right\}$. Since these are the expansion coefficients of $\varphi_{j}$ with respect to $\left\{\phi_{k}\right\}_{k \in K}$, this set is countable. Hence the set $\tilde{K}=\bigcup_{j \in J} K_{j}$ is countable as well. But $k \in K \backslash \tilde{K}$ implies $\phi_{k}=0$ and hence $\tilde{K}=K$.

## We will assume all Hilbert spaces to be separable.

In particular, it can be shown that $L^{2}(M, d \mu)$ is separable. Moreover, it turns out that, up to unitary equivalence, there is only one (separable) infinite dimensional Hilbert space:

Let $\mathfrak{H}$ be an infinite dimensional Hilbert space and let $\left\{\varphi_{j}\right\}_{j \in \mathbb{N}}$ be any orthogonal basis. Then the map $U: \mathfrak{H} \rightarrow \ell^{2}(\mathbb{N}), \psi \mapsto\left(\left\langle\varphi_{j}, \psi\right\rangle\right)_{j \in \mathbb{N}}$ is unitary (by Theorem 1.3 (iii)). In particular,

Theorem 1.6. Any separable infinite dimensional Hilbert space is unitarily equivalent to $\ell^{2}(\mathbb{N})$.

Let me remark that if $\mathfrak{H}$ is not separable, there still exists an orthonormal basis. However, the proof requires Zorn's lemma: The collection of all orthonormal sets in $\mathfrak{H}$ can be partially ordered by inclusion. Moreover, any linearly ordered chain has an upper bound (the union of all sets in the chain). Hence Zorn's lemma implies the existence of a maximal element, that is, an orthonormal basis.

Problem 1.2. Let $\left\{\varphi_{j}\right\}$ be some orthonormal basis. Show that a bounded linear operator $A$ is uniquely determined by its matrix elements $A_{j k}=$ $\left\langle\varphi_{j}, A \varphi_{k}\right\rangle$ with respect to this basis.

Problem 1.3. Show that $\mathfrak{L}(\mathfrak{H})$ is not separable if $\mathfrak{H}$ is infinite dimensional.

### 1.3. The projection theorem and the Riesz lemma

Let $M \subseteq \mathfrak{H}$ be a subset. Then $M^{\perp}=\{\psi \mid\langle\varphi, \psi\rangle=0, \forall \varphi \in M\}$ is called the orthogonal complement of $M$. By continuity of the scalar product it follows that $M^{\perp}$ is a closed linear subspace and by linearity that $(\overline{\operatorname{span}(M)})^{\perp}=M^{\perp}$. For example we have $\mathfrak{H}^{\perp}=\{0\}$ since any vector in $\mathfrak{H}^{\perp}$ must be in particular orthogonal to all vectors in some orthonormal basis.

Theorem 1.7 (Projection theorem). Let $M$ be a closed linear subspace of a Hilbert space $\mathfrak{H}$. Then every $\psi \in \mathfrak{H}$ can be uniquely written as $\psi=\psi_{\|}+\psi_{\perp}$ with $\psi_{\|} \in M$ and $\psi_{\perp} \in M^{\perp}$. One writes

$$
\begin{equation*}
M \oplus M^{\perp}=\mathfrak{H} \tag{1.28}
\end{equation*}
$$

in this situation.
Proof. Since $M$ is closed, it is a Hilbert space and has an orthonormal basis $\left\{\varphi_{j}\right\}_{j \in J}$. Hence the result follows from Theorem 1.2.

In other words, to every $\psi \in \mathfrak{H}$ we can assign a unique vector $\psi_{\|}$which is the vector in $M$ closest to $\psi$. The rest, $\psi-\psi_{\|}$, lies in $M^{\perp}$. The operator $P_{M} \psi=\psi_{\|}$is called the orthogonal projection corresponding to $M$. Note that we have

$$
\begin{equation*}
P_{M}^{2}=P_{M} \quad \text { and } \quad\left\langle P_{M} \psi, \varphi\right\rangle=\left\langle\psi, P_{M} \varphi\right\rangle \tag{1.29}
\end{equation*}
$$

since $\left\langle P_{M} \psi, \varphi\right\rangle=\left\langle\psi_{\|}, \varphi_{\|}\right\rangle=\left\langle\psi, P_{M} \varphi\right\rangle$. Clearly we have $P_{M^{\perp}} \psi=\psi-$ $P_{M} \psi=\psi_{\perp}$. Furthermore, (1.29) uniquely characterizes orthogonal projections (Problem 1.6).

Moreover, we see that the vectors in a closed subspace $M$ are precisely those which are orthogonal to all vectors in $M^{\perp}$; that is, $M^{\perp \perp}=M$. If $M$ is an arbitrary subset, we have at least

$$
\begin{equation*}
M^{\perp \perp}=\overline{\operatorname{span}(M)} . \tag{1.30}
\end{equation*}
$$

Note that by $\mathfrak{H}^{\perp}=\{0\}$ we see that $M^{\perp}=\{0\}$ if and only if $M$ is total.
Finally we turn to linear functionals, that is, to operators $\ell: \mathfrak{H} \rightarrow$ $\mathbb{C}$. By the Cauchy-Schwarz inequality we know that $\ell_{\varphi}: \psi \mapsto\langle\varphi, \psi\rangle$ is a bounded linear functional (with norm $\|\varphi\|$ ). It turns out that in a Hilbert space every bounded linear functional can be written in this way.
Theorem 1.8 (Riesz lemma). Suppose $\ell$ is a bounded linear functional on a Hilbert space $\mathfrak{H}$. Then there is a unique vector $\varphi \in \mathfrak{H}$ such that $\ell(\psi)=\langle\varphi, \psi\rangle$ for all $\psi \in \mathfrak{H}$. In other words, a Hilbert space is equivalent to its own dual space $\mathfrak{H}^{*}=\mathfrak{H}$.

Proof. If $\ell \equiv 0$, we can choose $\varphi=0$. Otherwise $\operatorname{Ker}(\ell)=\{\psi \mid \ell(\psi)=0\}$ is a proper subspace and we can find a unit vector $\tilde{\varphi} \in \operatorname{Ker}(\ell)^{\perp}$. For every $\psi \in \mathfrak{H}$ we have $\ell(\psi) \tilde{\varphi}-\ell(\tilde{\varphi}) \psi \in \operatorname{Ker}(\ell)$ and hence

$$
0=\langle\tilde{\varphi}, \ell(\psi) \tilde{\varphi}-\ell(\tilde{\varphi}) \psi\rangle=\ell(\psi)-\ell(\tilde{\varphi})\langle\tilde{\varphi}, \psi\rangle .
$$

In other words, we can choose $\varphi=\ell(\tilde{\varphi})^{*} \tilde{\varphi}$. To see uniqueness, let $\varphi_{1}, \varphi_{2}$ be two such vectors. Then $\left\langle\varphi_{1}-\varphi_{2}, \psi\right\rangle=\left\langle\varphi_{1}, \psi\right\rangle-\left\langle\varphi_{2}, \psi\right\rangle=\ell(\psi)-\ell(\psi)=0$ for any $\psi \in \mathfrak{H}$, which shows $\varphi_{1}-\varphi_{2} \in \mathfrak{H}^{\perp}=\{0\}$.

The following easy consequence is left as an exercise.
Corollary 1.9. Suppose $s$ is a bounded sesquilinear form; that is,

$$
\begin{equation*}
|s(\psi, \varphi)| \leq C\|\psi\|\|\varphi\| . \tag{1.31}
\end{equation*}
$$

Then there is a unique bounded operator $A$ such that

$$
\begin{equation*}
s(\psi, \varphi)=\langle A \psi, \varphi\rangle . \tag{1.32}
\end{equation*}
$$

Moreover, $\|A\| \leq C$.
Note that by the polarization identity (Problem 0.14), $A$ is already uniquely determined by its quadratic form $q_{A}(\psi)=\langle\psi, A \psi\rangle$.

Problem 1.4. Suppose $U: \mathfrak{H} \rightarrow \mathfrak{H}$ is unitary and $M \subseteq \mathfrak{H}$. Show that $U M^{\perp}=(U M)^{\perp}$.

Problem 1.5. Show that an orthogonal projection $P_{M} \neq 0$ has norm one.
Problem 1.6. Suppose $P \in \mathfrak{L}$ satisfies

$$
P^{2}=P \quad \text { and } \quad\langle P \psi, \varphi\rangle=\langle\psi, P \varphi\rangle
$$

and set $M=\operatorname{Ran}(P)$. Show

- $P \psi=\psi$ for $\psi \in M$ and $M$ is closed,
- $\varphi \in M^{\perp}$ implies $P \varphi \in M^{\perp}$ and thus $P \varphi=0$, and conclude $P=P_{M}$.

Problem 1.7. Let $P_{1}, P_{2}$ be two orthogonal projections. Show that $P_{1} \leq P_{2}$ (that is, $\left\langle\psi, P_{1} \psi\right\rangle \leq\left\langle\psi, P_{2} \psi\right\rangle$ ) if and only if $\operatorname{Ran}\left(P_{1}\right) \subseteq \operatorname{Ran}\left(P_{2}\right)$. Show in this case that the two projections commute (that is, $P_{1} P_{2}=P_{2} P_{1}$ ) and that $P_{2}-P_{1}$ is also a projection. (Hints: $\left\|P_{j} \psi\right\|=\|\psi\|$ if and only if $P_{j} \psi=\psi$ and $\operatorname{Ran}\left(P_{1}\right) \subseteq \operatorname{Ran}\left(P_{2}\right)$ if and only if $P_{2} P_{1}=P_{1}$.)

Problem 1.8. Show $P: L^{2}(\mathbb{R}) \rightarrow L^{2}(\mathbb{R}), f(x) \mapsto \frac{1}{2}(f(x)+f(-x))$ is a projection. Compute its range and kernel.

Problem 1.9. Prove Corollary 1.9.
Problem 1.10. Consider the sesquilinear form

$$
B(f, g)=\int_{0}^{1}\left(\int_{0}^{x} f(t)^{*} d t\right)\left(\int_{0}^{x} g(t) d t\right) d x
$$

in $L^{2}(0,1)$. Show that it is bounded and find the corresponding operator $A$. (Hint: Partial integration.)

### 1.4. Orthogonal sums and tensor products

Given two Hilbert spaces $\mathfrak{H}_{1}$ and $\mathfrak{H}_{2}$, we define their orthogonal sum $\mathfrak{H}_{1} \oplus \mathfrak{H}_{2}$ to be the set of all pairs $\left(\psi_{1}, \psi_{2}\right) \in \mathfrak{H}_{1} \times \mathfrak{H}_{2}$ together with the scalar product

$$
\begin{equation*}
\left\langle\left(\varphi_{1}, \varphi_{2}\right),\left(\psi_{1}, \psi_{2}\right)\right\rangle=\left\langle\varphi_{1}, \psi_{1}\right\rangle_{1}+\left\langle\varphi_{2}, \psi_{2}\right\rangle_{2} \tag{1.33}
\end{equation*}
$$

It is left as an exercise to verify that $\mathfrak{H}_{1} \oplus \mathfrak{H}_{2}$ is again a Hilbert space. Moreover, $\mathfrak{H}_{1}$ can be identified with $\left\{\left(\psi_{1}, 0\right) \mid \psi_{1} \in \mathfrak{H}_{1}\right\}$ and we can regard $\mathfrak{H}_{1}$ as a subspace of $\mathfrak{H}_{1} \oplus \mathfrak{H}_{2}$, and similarly for $\mathfrak{H}_{2}$. It is also customary to write $\psi_{1}+\psi_{2}$ instead of $\left(\psi_{1}, \psi_{2}\right)$.

More generally, let $\mathfrak{H}_{j}, j \in \mathbb{N}$, be a countable collection of Hilbert spaces and define

$$
\begin{equation*}
\bigoplus_{j=1}^{\infty} \mathfrak{H}_{j}=\left\{\sum_{j=1}^{\infty} \psi_{j} \mid \psi_{j} \in \mathfrak{H}_{j}, \sum_{j=1}^{\infty}\left\|\psi_{j}\right\|_{j}^{2}<\infty\right\} \tag{1.34}
\end{equation*}
$$

which becomes a Hilbert space with the scalar product

$$
\begin{equation*}
\left\langle\sum_{j=1}^{\infty} \varphi_{j}, \sum_{j=1}^{\infty} \psi_{j}\right\rangle=\sum_{j=1}^{\infty}\left\langle\varphi_{j}, \psi_{j}\right\rangle_{j} \tag{1.35}
\end{equation*}
$$

Example. $\bigoplus_{j=1}^{\infty} \mathbb{C}=\ell^{2}(\mathbb{N})$.
Similarly, if $\mathfrak{H}$ and $\tilde{\mathfrak{H}}$ are two Hilbert spaces, we define their tensor product as follows: The elements should be products $\psi \otimes \tilde{\psi}$ of elements $\psi \in \mathfrak{H}$
and $\tilde{\psi} \in \tilde{\mathfrak{H}}$. Hence we start with the set of all finite linear combinations of elements of $\mathfrak{H} \times \tilde{\mathfrak{H}}$ :

$$
\begin{equation*}
\mathcal{F}(\mathfrak{H}, \tilde{\mathfrak{H}})=\left\{\sum_{j=1}^{n} \alpha_{j}\left(\psi_{j}, \tilde{\psi}_{j}\right) \mid\left(\psi_{j}, \tilde{\psi}_{j}\right) \in \mathfrak{H} \times \tilde{\mathfrak{H}}, \alpha_{j} \in \mathbb{C}\right\} . \tag{1.36}
\end{equation*}
$$

Since we want $\left(\psi_{1}+\psi_{2}\right) \otimes \tilde{\psi}=\psi_{1} \otimes \tilde{\psi}+\psi_{2} \otimes \tilde{\psi}, \psi \otimes\left(\tilde{\psi}_{1}+\tilde{\psi}_{2}\right)=\psi \otimes \tilde{\psi}_{1}+\psi \otimes \tilde{\psi}_{2}$, and $(\alpha \psi) \otimes \tilde{\psi}=\psi \otimes(\alpha \tilde{\psi})$, we consider $\mathcal{F}(\mathfrak{H}, \tilde{\mathfrak{H}}) / \mathcal{N}(\mathfrak{H}, \tilde{\mathfrak{H}})$, where

$$
\begin{equation*}
\mathcal{N}(\mathfrak{H}, \tilde{\mathfrak{H}})=\operatorname{span}\left\{\sum_{j, k=1}^{n} \alpha_{j} \beta_{k}\left(\psi_{j}, \tilde{\psi}_{k}\right)-\left(\sum_{j=1}^{n} \alpha_{j} \psi_{j}, \sum_{k=1}^{n} \beta_{k} \tilde{\psi}_{k}\right)\right\} \tag{1.37}
\end{equation*}
$$

and write $\psi \otimes \tilde{\psi}$ for the equivalence class of $(\psi, \tilde{\psi})$.
Next we define

$$
\begin{equation*}
\langle\psi \otimes \tilde{\psi}, \phi \otimes \tilde{\phi}\rangle=\langle\psi, \phi\rangle\langle\tilde{\psi}, \tilde{\phi}\rangle \tag{1.38}
\end{equation*}
$$

which extends to a sesquilinear form on $\mathcal{F}(\mathfrak{H}, \tilde{\mathfrak{H}}) / \mathcal{N}(\mathfrak{H}, \tilde{\mathfrak{H}})$. To show that we obtain a scalar product, we need to ensure positivity. Let $\psi=\sum_{i} \alpha_{i} \psi_{i} \otimes \tilde{\psi}_{i} \neq$ 0 and pick orthonormal bases $\varphi_{j}, \tilde{\varphi}_{k}$ for $\operatorname{span}\left\{\psi_{i}\right\}, \operatorname{span}\left\{\tilde{\psi}_{i}\right\}$, respectively. Then

$$
\begin{equation*}
\psi=\sum_{j, k} \alpha_{j k} \varphi_{j} \otimes \tilde{\varphi}_{k}, \quad \alpha_{j k}=\sum_{i} \alpha_{i}\left\langle\varphi_{j}, \psi_{i}\right\rangle\left\langle\tilde{\varphi}_{k}, \tilde{\psi}_{i}\right\rangle \tag{1.39}
\end{equation*}
$$

and we compute

$$
\begin{equation*}
\langle\psi, \psi\rangle=\sum_{j, k}\left|\alpha_{j k}\right|^{2}>0 \tag{1.40}
\end{equation*}
$$

The completion of $\mathcal{F}(\mathfrak{H}, \tilde{\mathfrak{H}}) / \mathcal{N}(\mathfrak{H}, \tilde{\mathfrak{H}})$ with respect to the induced norm is called the tensor product $\mathfrak{H} \otimes \tilde{\mathfrak{H}}$ of $\mathfrak{H}$ and $\tilde{\mathfrak{H}}$.
Lemma 1.10. If $\varphi_{j}, \tilde{\varphi}_{k}$ are orthonormal bases for $\mathfrak{H}$, $\tilde{\mathfrak{H}}$, respectively, then $\varphi_{j} \otimes \tilde{\varphi}_{k}$ is an orthonormal basis for $\mathfrak{H} \otimes \tilde{\mathfrak{H}}$.

Proof. That $\varphi_{j} \otimes \tilde{\varphi}_{k}$ is an orthonormal set is immediate from (1.38). Moreover, since $\operatorname{span}\left\{\varphi_{j}\right\}, \operatorname{span}\left\{\tilde{\varphi}_{k}\right\}$ are dense in $\mathfrak{H}, \tilde{\mathfrak{H}}$, respectively, it is easy to see that $\varphi_{j} \otimes \tilde{\varphi}_{k}$ is dense in $\mathcal{F}(\mathfrak{H}, \tilde{\mathfrak{H}}) / \mathcal{N}(\mathfrak{H}, \tilde{\mathfrak{H}})$. But the latter is dense in $\mathfrak{H} \otimes \tilde{\mathfrak{H}}$.

Example. We have $\mathfrak{H} \otimes \mathbb{C}^{n}=\mathfrak{H}^{n}$.
Example. Let $(M, d \mu)$ and $(\tilde{M}, d \tilde{\mu})$ be two measure spaces. Then we have $L^{2}(M, d \mu) \otimes L^{2}(\tilde{M}, d \tilde{\mu})=L^{2}(M \times \tilde{M}, d \mu \times d \tilde{\mu})$.

Clearly we have $L^{2}(M, d \mu) \otimes L^{2}(\tilde{M}, d \tilde{\mu}) \subseteq L^{2}(M \times \tilde{M}, d \mu \times d \tilde{\mu})$. Now take an orthonormal basis $\varphi_{j} \otimes \tilde{\varphi}_{k}$ for $L^{2}(M, d \mu) \otimes L^{2}(\tilde{M}, d \tilde{\mu})$ as in our previous lemma. Then

$$
\begin{equation*}
\int_{M} \int_{\tilde{M}}\left(\varphi_{j}(x) \tilde{\varphi}_{k}(y)\right)^{*} f(x, y) d \mu(x) d \tilde{\mu}(y)=0 \tag{1.41}
\end{equation*}
$$

implies

$$
\begin{equation*}
\int_{M} \varphi_{j}(x)^{*} f_{k}(x) d \mu(x)=0, \quad f_{k}(x)=\int_{\tilde{M}} \tilde{\varphi}_{k}(y)^{*} f(x, y) d \tilde{\mu}(y) \tag{1.42}
\end{equation*}
$$

and hence $f_{k}(x)=0 \mu$-a.e. $x$. But this implies $f(x, y)=0$ for $\mu$-a.e. $x$ and $\tilde{\mu}$-a.e. $y$ and thus $f=0$. Hence $\varphi_{j} \otimes \tilde{\varphi}_{k}$ is a basis for $L^{2}(M \times \tilde{M}, d \mu \times d \tilde{\mu})$ and equality follows.

It is straightforward to extend the tensor product to any finite number of Hilbert spaces. We even note

$$
\begin{equation*}
\left(\bigoplus_{j=1}^{\infty} \mathfrak{H}_{j}\right) \otimes \mathfrak{H}=\bigoplus_{j=1}^{\infty}\left(\mathfrak{H}_{j} \otimes \mathfrak{H}\right), \tag{1.43}
\end{equation*}
$$

where equality has to be understood in the sense that both spaces are unitarily equivalent by virtue of the identification

$$
\begin{equation*}
\left(\sum_{j=1}^{\infty} \psi_{j}\right) \otimes \psi=\sum_{j=1}^{\infty} \psi_{j} \otimes \psi \tag{1.44}
\end{equation*}
$$

Problem 1.11. Show that $\psi \otimes \tilde{\psi}=0$ if and only if $\psi=0$ or $\tilde{\psi}=0$.
Problem 1.12. We have $\psi \otimes \tilde{\psi} \underset{\sim}{=} \phi \otimes \tilde{\phi} \neq 0$ if and only if there is some $\alpha \in \mathbb{C} \backslash\{0\}$ such that $\psi=\alpha \phi$ and $\tilde{\psi}=\alpha^{-1} \tilde{\phi}$.
Problem 1.13. Show (1.43)

### 1.5. The $C^{*}$ algebra of bounded linear operators

We start by introducing a conjugation for operators on a Hilbert space $\mathfrak{H}$. Let $A \in \mathfrak{L}(\mathfrak{H})$. Then the adjoint operator is defined via

$$
\begin{equation*}
\left\langle\varphi, A^{*} \psi\right\rangle=\langle A \varphi, \psi\rangle \tag{1.45}
\end{equation*}
$$

(compare Corollary 1.9).
Example. If $\mathfrak{H}=\mathbb{C}^{n}$ and $A=\left(a_{j k}\right)_{1 \leq j, k \leq n}$, then $A^{*}=\left(a_{k j}^{*}\right)_{1 \leq j, k \leq n}$.
Lemma 1.11. Let $A, B \in \mathfrak{L}(\mathfrak{H})$. Then
(i) $(A+B)^{*}=A^{*}+B^{*}, \quad(\alpha A)^{*}=\alpha^{*} A^{*}$,
(ii) $A^{* *}=A$,
(iii) $(A B)^{*}=B^{*} A^{*}$,
(iv) $\|A\|=\left\|A^{*}\right\|$ and $\|A\|^{2}=\left\|A^{*} A\right\|=\left\|A A^{*}\right\|$.

Proof. (i) and (ii) are obvious. (iii) follows from $\langle\varphi,(A B) \psi\rangle=\left\langle A^{*} \varphi, B \psi\right\rangle=$ $\left\langle B^{*} A^{*} \varphi, \psi\right\rangle$. (iv) follows from

$$
\left\|A^{*}\right\|=\sup _{\|\varphi\|=\|\psi\|=1}\left|\left\langle\psi, A^{*} \varphi\right\rangle\right|=\sup _{\|\varphi\|=\|\psi\|=1}|\langle A \psi, \varphi\rangle|=\|A\|
$$

and

$$
\begin{aligned}
\left\|A^{*} A\right\| & =\sup _{\|\varphi\|=\|\psi\|=1}\left|\left\langle\varphi, A^{*} A \psi\right\rangle\right|=\sup _{\|\varphi\|=\|\psi\|=1}|\langle A \varphi, A \psi\rangle| \\
& =\sup _{\|\varphi\|=1}\|A \varphi\|^{2}=\|A\|^{2},
\end{aligned}
$$

where we have used $\|\varphi\|=\sup _{\|\psi\|=1}|\langle\psi, \varphi\rangle|$.
As a consequence of $\left\|A^{*}\right\|=\|A\|$ observe that taking the adjoint is continuous.

In general, a Banach algebra $\mathcal{A}$ together with an involution

$$
\begin{equation*}
(a+b)^{*}=a^{*}+b^{*}, \quad(\alpha a)^{*}=\alpha^{*} a^{*}, \quad a^{* *}=a, \quad(a b)^{*}=b^{*} a^{*} \tag{1.46}
\end{equation*}
$$

satisfying

$$
\begin{equation*}
\|a\|^{2}=\left\|a^{*} a\right\| \tag{1.47}
\end{equation*}
$$

is called a $C^{*}$ algebra. The element $a^{*}$ is called the adjoint of $a$. Note that $\left\|a^{*}\right\|=\|a\|$ follows from (1.47) and $\left\|a a^{*}\right\| \leq\|a\|\left\|a^{*}\right\|$.

Any subalgebra which is also closed under involution is called a *subalgebra. An ideal is a subspace $\mathcal{I} \subseteq \mathcal{A}$ such that $a \in \mathcal{I}, b \in \mathcal{A}$ imply $a b \in \mathcal{I}$ and $b a \in \mathcal{I}$. If it is closed under the adjoint map, it is called a $*$-ideal. Note that if there is an identity $e$, we have $e^{*}=e$ and hence $\left(a^{-1}\right)^{*}=\left(a^{*}\right)^{-1}$ (show this).
Example. The continuous functions $C(I)$ together with complex conjugation form a commutative $C^{*}$ algebra.

An element $a \in \mathcal{A}$ is called normal if $a a^{*}=a^{*} a$, self-adjoint if $a=a^{*}$, unitary if $a a^{*}=a^{*} a=\mathbb{I}$, an (orthogonal) projection if $a=a^{*}=a^{2}$, and positive if $a=b b^{*}$ for some $b \in \mathcal{A}$. Clearly both self-adjoint and unitary elements are normal.

Problem 1.14. Let $A \in \mathfrak{L}(\mathfrak{H})$. Show that $A$ is normal if and only if

$$
\|A \psi\|=\left\|A^{*} \psi\right\|, \quad \forall \psi \in \mathfrak{H} .
$$

(Hint: Problem 0.14.)
Problem 1.15. Show that $U: \mathfrak{H} \rightarrow \mathfrak{H}$ is unitary if and only if $U^{-1}=U^{*}$.
Problem 1.16. Compute the adjoint of

$$
S: \ell^{2}(\mathbb{N}) \rightarrow \ell^{2}(\mathbb{N}), \quad\left(a_{1}, a_{2}, a_{3}, \ldots\right) \mapsto\left(0, a_{1}, a_{2}, \ldots\right)
$$

### 1.6. Weak and strong convergence

Sometimes a weaker notion of convergence is useful: We say that $\psi_{n}$ converges weakly to $\psi$ and write

$$
\begin{equation*}
\underset{n \rightarrow \infty}{\left.\mathrm{w}-\lim _{n \rightarrow} \psi_{n}=\psi \quad \text { or } \quad \psi_{n} \rightharpoonup \psi, \psi\right)} \tag{1.48}
\end{equation*}
$$

if $\left\langle\varphi, \psi_{n}\right\rangle \rightarrow\langle\varphi, \psi\rangle$ for every $\varphi \in \mathfrak{H}$ (show that a weak limit is unique).
Example. Let $\varphi_{n}$ be an (infinite) orthonormal set. Then $\left\langle\psi, \varphi_{n}\right\rangle \rightarrow 0$ for every $\psi$ since these are just the expansion coefficients of $\psi$. ( $\varphi_{n}$ does not converge to 0 , since $\left\|\varphi_{n}\right\|=1$.)

Clearly $\psi_{n} \rightarrow \psi$ implies $\psi_{n} \rightharpoonup \psi$ and hence this notion of convergence is indeed weaker. Moreover, the weak limit is unique, since $\left\langle\varphi, \psi_{n}\right\rangle \rightarrow\langle\varphi, \psi\rangle$ and $\left\langle\varphi, \psi_{n}\right\rangle \rightarrow\langle\varphi, \tilde{\psi}\rangle$ imply $\langle\varphi,(\psi-\tilde{\psi})\rangle=0$. A sequence $\psi_{n}$ is called a weak Cauchy sequence if $\left\langle\varphi, \psi_{n}\right\rangle$ is Cauchy for every $\varphi \in \mathfrak{H}$.

Lemma 1.12. Let $\mathfrak{H}$ be a Hilbert space.
(i) $\psi_{n} \rightharpoonup \psi$ implies $\|\psi\| \leq \liminf \left\|\psi_{n}\right\|$.
(ii) Every weak Cauchy sequence $\psi_{n}$ is bounded: $\left\|\psi_{n}\right\| \leq C$.
(iii) Every weak Cauchy sequence converges weakly.
(iv) For a weakly convergent sequence $\psi_{n} \rightharpoonup \psi$ we have $\psi_{n} \rightarrow \psi$ if and only if $\lim \sup \left\|\psi_{n}\right\| \leq\|\psi\|$.

Proof. (i) Observe

$$
\|\psi\|^{2}=\langle\psi, \psi\rangle=\liminf \left\langle\psi, \psi_{n}\right\rangle \leq\|\psi\| \lim \inf \left\|\psi_{n}\right\| .
$$

(ii) For every $\varphi$ we have that $\left|\left\langle\varphi, \psi_{n}\right\rangle\right| \leq C(\varphi)$ is bounded. Hence by the uniform boundedness principle we have $\left\|\psi_{n}\right\|=\left\|\left\langle\psi_{n},.\right\rangle\right\| \leq C$.
(iii) Let $\varphi_{m}$ be an orthonormal basis and define $c_{m}=\lim _{n \rightarrow \infty}\left\langle\varphi_{m}, \psi_{n}\right\rangle$. Then $\psi=\sum_{m} c_{m} \varphi_{m}$ is the desired limit.
(iv) By (i) we have $\lim \left\|\psi_{n}\right\|=\|\psi\|$ and hence

$$
\left\|\psi-\psi_{n}\right\|^{2}=\|\psi\|^{2}-2 \operatorname{Re}\left(\left\langle\psi, \psi_{n}\right\rangle\right)+\left\|\psi_{n}\right\|^{2} \rightarrow 0 .
$$

The converse is straightforward.
Clearly an orthonormal basis does not have a norm convergent subsequence. Hence the unit ball in an infinite dimensional Hilbert space is never compact. However, we can at least extract weakly convergent subsequences:

Lemma 1.13. Let $\mathfrak{H}$ be a Hilbert space. Every bounded sequence $\psi_{n}$ has a weakly convergent subsequence.

Proof. Let $\varphi_{k}$ be an orthonormal basis. Then by the usual diagonal sequence argument we can find a subsequence $\psi_{n_{m}}$ such that $\left\langle\varphi_{k}, \psi_{n_{m}}\right\rangle$ converges for all $k$. Since $\psi_{n}$ is bounded, $\left\langle\varphi, \psi_{n_{m}}\right\rangle$ converges for every $\varphi \in \mathfrak{H}$ and hence $\psi_{n_{m}}$ is a weak Cauchy sequence.

Finally, let me remark that similar concepts can be introduced for operators. This is of particular importance for the case of unbounded operators, where convergence in the operator norm makes no sense at all.

A sequence of operators $A_{n}$ is said to converge strongly to $A$,

$$
\begin{equation*}
\underset{n \rightarrow \infty}{\mathrm{~s}-\lim _{n}} A_{n}=A \quad: \Leftrightarrow \quad A_{n} \psi \rightarrow A \psi \quad \forall x \in \mathfrak{D}(A) \subseteq \mathfrak{D}\left(A_{n}\right) \tag{1.49}
\end{equation*}
$$

It is said to converge weakly to $A$,

$$
\begin{equation*}
\underset{n \rightarrow \infty}{\mathrm{w}-\lim _{n}} A_{n}=A \quad: \Leftrightarrow \quad A_{n} \psi \rightharpoonup A \psi \quad \forall \psi \in \mathfrak{D}(A) \subseteq \mathfrak{D}\left(A_{n}\right) . \tag{1.50}
\end{equation*}
$$

Clearly norm convergence implies strong convergence and strong convergence implies weak convergence.
Example. Consider the operator $S_{n} \in \mathfrak{L}\left(\ell^{2}(\mathbb{N})\right)$ which shifts a sequence $n$ places to the left, that is,

$$
\begin{equation*}
S_{n}\left(x_{1}, x_{2}, \ldots\right)=\left(x_{n+1}, x_{n+2}, \ldots\right), \tag{1.51}
\end{equation*}
$$

and the operator $S_{n}^{*} \in \mathfrak{L}\left(\ell^{2}(\mathbb{N})\right)$ which shifts a sequence $n$ places to the right and fills up the first $n$ places with zeros, that is,

$$
\begin{equation*}
S_{n}^{*}\left(x_{1}, x_{2}, \ldots\right)=(\underbrace{0, \ldots, 0}_{n \text { places }}, x_{1}, x_{2}, \ldots) . \tag{1.52}
\end{equation*}
$$

Then $S_{n}$ converges to zero strongly but not in norm (since $\left\|S_{n}\right\|=1$ ) and $S_{n}^{*}$ converges weakly to zero (since $\left\langle\varphi, S_{n}^{*} \psi\right\rangle=\left\langle S_{n} \varphi, \psi\right\rangle$ ) but not strongly (since $\left\|S_{n}^{*} \psi\right\|=\|\psi\|$ ).

Note that this example also shows that taking adjoints is not continuous with respect to strong convergence! If $A_{n} \xrightarrow{s} A$, we only have

$$
\begin{equation*}
\left\langle\varphi, A_{n}^{*} \psi\right\rangle=\left\langle A_{n} \varphi, \psi\right\rangle \rightarrow\langle A \varphi, \psi\rangle=\left\langle\varphi, A^{*} \psi\right\rangle \tag{1.53}
\end{equation*}
$$

and hence $A_{n}^{*} \rightharpoonup A^{*}$ in general. However, if $A_{n}$ and $A$ are normal, we have

$$
\begin{equation*}
\left\|\left(A_{n}-A\right)^{*} \psi\right\|=\left\|\left(A_{n}-A\right) \psi\right\| \tag{1.54}
\end{equation*}
$$

and hence $A_{n}^{*} \xrightarrow{s} A^{*}$ in this case. Thus at least for normal operators taking adjoints is continuous with respect to strong convergence.

Lemma 1.14. Suppose $A_{n}$ is a sequence of bounded operators.
(i) $s-\lim _{n \rightarrow \infty} A_{n}=A$ implies $\|A\| \leq \liminf _{n \rightarrow \infty}\left\|A_{n}\right\|$.
(ii) Every strong Cauchy sequence $A_{n}$ is bounded: $\left\|A_{n}\right\| \leq C$.
(iii) If $A_{n} \psi \rightarrow A \psi$ for $\psi$ in some dense set and $\left\|A_{n}\right\| \leq C$, then $\mathrm{s}-\lim _{n \rightarrow \infty} A_{n}=A$.
The same result holds if strong convergence is replaced by weak convergence.
Proof. (i) follows from

$$
\|A \psi\|=\lim _{n \rightarrow \infty}\left\|A_{n} \psi\right\| \leq \liminf _{n \rightarrow \infty}\left\|A_{n}\right\|
$$

for every $\psi$ with $\|\psi\|=1$.
(ii) follows as in Lemma 1.12 (i).
(iii) Just use

$$
\begin{aligned}
\left\|A_{n} \psi-A \psi\right\| & \leq\left\|A_{n} \psi-A_{n} \varphi\right\|+\left\|A_{n} \varphi-A \varphi\right\|+\|A \varphi-A \psi\| \\
& \leq 2 C\|\psi-\varphi\|+\left\|A_{n} \varphi-A \varphi\right\|
\end{aligned}
$$

and choose $\varphi$ in the dense subspace such that $\|\psi-\varphi\| \leq \frac{\varepsilon}{4 C}$ and $n$ large such that $\left\|A_{n} \varphi-A \varphi\right\| \leq \frac{\varepsilon}{2}$.

The case of weak convergence is left as an exercise. (Hint: (2.14).)
Problem 1.17. Suppose $\psi_{n} \rightarrow \psi$ and $\varphi_{n} \rightharpoonup \varphi$. Then $\left\langle\psi_{n}, \varphi_{n}\right\rangle \rightarrow\langle\psi, \varphi\rangle$.
Problem 1.18. Let $\left\{\varphi_{j}\right\}_{j=1}^{\infty}$ be some orthonormal basis. Show that $\psi_{n} \rightharpoonup \psi$ if and only if $\psi_{n}$ is bounded and $\left\langle\varphi_{j}, \psi_{n}\right\rangle \rightarrow\left\langle\varphi_{j}, \psi\right\rangle$ for every $j$. Show that this is wrong without the boundedness assumption.

Problem 1.19. A subspace $M \subseteq \mathfrak{H}$ is closed if and only if every weak Cauchy sequence in $M$ has a limit in $M$. (Hint: $\bar{M}=M^{\perp \perp}$.)

### 1.7. Appendix: The Stone-Weierstraß theorem

In case of a self-adjoint operator, the spectral theorem will show that the closed $*$-subalgebra generated by this operator is isomorphic to the $C^{*}$ algebra of continuous functions $C(K)$ over some compact set. Hence it is important to be able to identify dense sets:

Theorem 1.15 (Stone-Weierstraß, real version). Suppose $K$ is a compact set and let $C(K, \mathbb{R})$ be the Banach algebra of continuous functions (with the sup norm).

If $F \subset C(K, \mathbb{R})$ contains the identity 1 and separates points (i.e., for every $x_{1} \neq x_{2}$ there is some function $f \in F$ such that $f\left(x_{1}\right) \neq f\left(x_{2}\right)$ ), then the algebra generated by $F$ is dense.

Proof. Denote by $A$ the algebra generated by $F$. Note that if $f \in \bar{A}$, we have $|f| \in \bar{A}$ : By the Weierstraß approximation theorem (Theorem 0.15) there is a polynomial $p_{n}(t)$ such that $\left||t|-p_{n}(t)\right|<\frac{1}{n}$ for $t \in f(K)$ and hence $p_{n}(f) \rightarrow|f|$.

In particular, if $f, g$ are in $\bar{A}$, we also have

$$
\max \{f, g\}=\frac{(f+g)+|f-g|}{2}, \quad \min \{f, g\}=\frac{(f+g)-|f-g|}{2}
$$

in $\bar{A}$.
Now fix $f \in C(K, \mathbb{R})$. We need to find some $f_{\varepsilon} \in \bar{A}$ with $\left\|f-f_{\varepsilon}\right\|_{\infty}<\varepsilon$.
First of all, since $A$ separates points, observe that for given $y, z \in K$ there is a function $f_{y, z} \in A$ such that $f_{y, z}(y)=f(y)$ and $f_{y, z}(z)=f(z)$ (show this). Next, for every $y \in K$ there is a neighborhood $U(y)$ such that

$$
f_{y, z}(x)>f(x)-\varepsilon, \quad x \in U(y),
$$

and since $K$ is compact, finitely many, say $U\left(y_{1}\right), \ldots, U\left(y_{j}\right)$, cover $K$. Then

$$
f_{z}=\max \left\{f_{y_{1}, z}, \ldots, f_{y_{j}, z}\right\} \in \bar{A}
$$

and satisfies $f_{z}>f-\varepsilon$ by construction. Since $f_{z}(z)=f(z)$ for every $z \in K$, there is a neighborhood $V(z)$ such that

$$
f_{z}(x)<f(x)+\varepsilon, \quad x \in V(z)
$$

and a corresponding finite cover $V\left(z_{1}\right), \ldots, V\left(z_{k}\right)$. Now

$$
f_{\varepsilon}=\min \left\{f_{z_{1}}, \ldots, f_{z_{k}}\right\} \in \bar{A}
$$

satisfies $f_{\varepsilon}<f+\varepsilon$. Since $f-\varepsilon<f_{z_{l}}<f_{\varepsilon}$, we have found a required function.

Theorem 1.16 (Stone-Weierstraß). Suppose $K$ is a compact set and let $C(K)$ be the $C^{*}$ algebra of continuous functions (with the sup norm).

If $F \subset C(K)$ contains the identity 1 and separates points, then the *subalgebra generated by $F$ is dense.

Proof. Just observe that $\tilde{F}=\{\operatorname{Re}(f), \operatorname{Im}(f) \mid f \in F\}$ satisfies the assumption of the real version. Hence any real-valued continuous functions can be approximated by elements from $\tilde{F}$, in particular this holds for the real and imaginary parts for any given complex-valued function.

Note that the additional requirement of being closed under complex conjugation is crucial: The functions holomorphic on the unit ball and continuous on the boundary separate points, but they are not dense (since the uniform limit of holomorphic functions is again holomorphic).

Corollary 1.17. Suppose $K$ is a compact set and let $C(K)$ be the $C^{*}$ algebra of continuous functions (with the sup norm).

If $F \subset C(K)$ separates points, then the closure of the $*$-subalgebra generated by $F$ is either $C(K)$ or $\left\{f \in C(K) \mid f\left(t_{0}\right)=0\right\}$ for some $t_{0} \in K$.

Proof. There are two possibilities: either all $f \in F$ vanish at one point $t_{0} \in K$ (there can be at most one such point since $F$ separates points) or there is no such point. If there is no such point, we can proceed as in the proof of the Stone-Weierstraß theorem to show that the identity can be approximated by elements in $\bar{A}$ (note that to show $|f| \in \bar{A}$ if $f \in \bar{A}$, we do not need the identity, since $p_{n}$ can be chosen to contain no constant term). If there is such a $t_{0}$, the identity is clearly missing from $\bar{A}$. However, adding the identity to $\bar{A}$, we get $\bar{A}+\mathbb{C}=C(K)$ and it is easy to see that $\bar{A}=\left\{f \in C(K) \mid f\left(t_{0}\right)=0\right\}$.
Problem 1.20. Show that the functions $\varphi_{n}(x)=\frac{1}{\sqrt{2 \pi}} \mathrm{e}^{\mathrm{i} n x}, n \in \mathbb{Z}$, form an orthonormal basis for $\mathfrak{H}=L^{2}(0,2 \pi)$.

Problem 1.21. Let $k \in \mathbb{N}$ and $I \subseteq \mathbb{R}$. Show that the $*$-subalgebra generated by $f_{z_{0}}(t)=\frac{1}{\left(t-z_{0}\right)^{k}}$ for one $z_{0} \in \mathbb{C}$ is dense in the $C^{*}$ algebra $C_{\infty}(I)$ of continuous functions vanishing at infinity

- for $I=\mathbb{R}$ if $z_{0} \in \mathbb{C} \backslash \mathbb{R}$ and $k=1,2$,
- for $I=[a, \infty)$ if $z_{0} \in(-\infty, a)$ and any $k$,
- for $I=(-\infty, a] \cup[b, \infty)$ if $z_{0} \in(a, b)$ and $k$ odd.
(Hint: Add $\infty$ to $\mathbb{R}$ to make it compact.)

## Self-adjointness and spectrum

### 2.1. Some quantum mechanics

In quantum mechanics, a single particle living in $\mathbb{R}^{3}$ is described by a complex-valued function (the wave function)

$$
\begin{equation*}
\psi(x, t), \quad(x, t) \in \mathbb{R}^{3} \times \mathbb{R} \tag{2.1}
\end{equation*}
$$

where $x$ corresponds to a point in space and $t$ corresponds to time. The quantity $\rho_{t}(x)=|\psi(x, t)|^{2}$ is interpreted as the probability density of the particle at the time $t$. In particular, $\psi$ must be normalized according to

$$
\begin{equation*}
\int_{\mathbb{R}^{3}}|\psi(x, t)|^{2} d^{3} x=1, \quad t \in \mathbb{R} . \tag{2.2}
\end{equation*}
$$

The location $x$ of the particle is a quantity which can be observed (i.e., measured) and is hence called observable. Due to our probabilistic interpretation, it is also a random variable whose expectation is given by

$$
\begin{equation*}
\mathbb{E}_{\psi}(x)=\int_{\mathbb{R}^{3}} x|\psi(x, t)|^{2} d^{3} x \tag{2.3}
\end{equation*}
$$

In a real life setting, it will not be possible to measure $x$ directly and one will only be able to measure certain functions of $x$. For example, it is possible to check whether the particle is inside a certain area $\Omega$ of space (e.g., inside a detector). The corresponding observable is the characteristic function $\chi_{\Omega}(x)$ of this set. In particular, the number

$$
\begin{equation*}
\mathbb{E}_{\psi}\left(\chi_{\Omega}\right)=\int_{\mathbb{R}^{3}} \chi_{\Omega}(x)|\psi(x, t)|^{2} d^{3} x=\int_{\Omega}|\psi(x, t)|^{2} d^{3} x \tag{2.4}
\end{equation*}
$$

corresponds to the probability of finding the particle inside $\Omega \subseteq \mathbb{R}^{3}$. An important point to observe is that, in contradistinction to classical mechanics, the particle is no longer localized at a certain point. In particular, the mean-square deviation (or variance) $\Delta_{\psi}(x)^{2}=\mathbb{E}_{\psi}\left(x^{2}\right)-\mathbb{E}_{\psi}(x)^{2}$ is always nonzero.

In general, the configuration space (or phase space) of a quantum system is a (complex) Hilbert space $\mathfrak{H}$ and the possible states of this system are represented by the elements $\psi$ having norm one, $\|\psi\|=1$.

An observable $a$ corresponds to a linear operator $A$ in this Hilbert space and its expectation, if the system is in the state $\psi$, is given by the real number

$$
\begin{equation*}
\mathbb{E}_{\psi}(A)=\langle\psi, A \psi\rangle=\langle A \psi, \psi\rangle \tag{2.5}
\end{equation*}
$$

where $\langle., .$.$\rangle denotes the scalar product of \mathfrak{H}$. Similarly, the mean-square deviation is given by

$$
\begin{equation*}
\Delta_{\psi}(A)^{2}=\mathbb{E}_{\psi}\left(A^{2}\right)-\mathbb{E}_{\psi}(A)^{2}=\left\|\left(A-\mathbb{E}_{\psi}(A)\right) \psi\right\|^{2} \tag{2.6}
\end{equation*}
$$

Note that $\Delta_{\psi}(A)$ vanishes if and only if $\psi$ is an eigenstate corresponding to the eigenvalue $\mathbb{E}_{\psi}(A)$; that is, $A \psi=\mathbb{E}_{\psi}(A) \psi$.

From a physical point of view, (2.5) should make sense for any $\psi \in \mathfrak{H}$. However, this is not in the cards as our simple example of one particle already shows. In fact, the reader is invited to find a square integrable function $\psi(x)$ for which $x \psi(x)$ is no longer square integrable. The deeper reason behind this nuisance is that $\mathbb{E}_{\psi}(x)$ can attain arbitrarily large values if the particle is not confined to a finite domain, which renders the corresponding operator unbounded. But unbounded operators cannot be defined on the entire Hilbert space in a natural way by the closed graph theorem (Theorem 2.8 below).

Hence, $A$ will only be defined on a subset $\mathfrak{D}(A) \subseteq \mathfrak{H}$ called the domain of $A$. Since we want $A$ to be defined for at least most states, we require $\mathfrak{D}(A)$ to be dense.

However, it should be noted that there is no general prescription for how to find the operator corresponding to a given observable.

Now let us turn to the time evolution of such a quantum mechanical system. Given an initial state $\psi(0)$ of the system, there should be a unique $\psi(t)$ representing the state of the system at time $t \in \mathbb{R}$. We will write

$$
\begin{equation*}
\psi(t)=U(t) \psi(0) \tag{2.7}
\end{equation*}
$$

Moreover, it follows from physical experiments that superposition of states holds; that is, $U(t)\left(\alpha_{1} \psi_{1}(0)+\alpha_{2} \psi_{2}(0)\right)=\alpha_{1} \psi_{1}(t)+\alpha_{2} \psi_{2}(t)\left(\left|\alpha_{1}\right|^{2}+\left|\alpha_{2}\right|^{2}=\right.$ 1). In other words, $U(t)$ should be a linear operator. Moreover, since $\psi(t)$
is a state (i.e., $\|\psi(t)\|=1$ ), we have

$$
\begin{equation*}
\|U(t) \psi\|=\|\psi\| . \tag{2.8}
\end{equation*}
$$

Such operators are called unitary. Next, since we have assumed uniqueness of solutions to the initial value problem, we must have

$$
\begin{equation*}
U(0)=\mathbb{I}, \quad U(t+s)=U(t) U(s) \tag{2.9}
\end{equation*}
$$

A family of unitary operators $U(t)$ having this property is called a oneparameter unitary group. In addition, it is natural to assume that this group is strongly continuous; that is,

$$
\begin{equation*}
\lim _{t \rightarrow t_{0}} U(t) \psi=U\left(t_{0}\right) \psi, \quad \psi \in \mathfrak{H} . \tag{2.10}
\end{equation*}
$$

Each such group has an infinitesimal generator defined by

$$
\begin{equation*}
H \psi=\lim _{t \rightarrow 0} \frac{\mathrm{i}}{t}(U(t) \psi-\psi), \quad \mathfrak{D}(H)=\left\{\psi \in \mathfrak{H} \left\lvert\, \lim _{t \rightarrow 0} \frac{1}{t}(U(t) \psi-\psi)\right. \text { exists }\right\} . \tag{2.11}
\end{equation*}
$$

This operator is called the Hamiltonian and corresponds to the energy of the system. If $\psi(0) \in \mathfrak{D}(H)$, then $\psi(t)$ is a solution of the Schrödinger equation (in suitable units)

$$
\begin{equation*}
\mathrm{i} \frac{d}{d t} \psi(t)=H \psi(t) . \tag{2.12}
\end{equation*}
$$

This equation will be the main subject of our course.
In summary, we have the following axioms of quantum mechanics.
Axiom 1. The configuration space of a quantum system is a complex separable Hilbert space $\mathfrak{H}$ and the possible states of this system are represented by the elements of $\mathfrak{H}$ which have norm one.

Axiom 2. Each observable $a$ corresponds to a linear operator $A$ defined maximally on a dense subset $\mathfrak{D}(A)$. Moreover, the operator corresponding to a polynomial $P_{n}(a)=\sum_{j=0}^{n} \alpha_{j} a^{j}, \alpha_{j} \in \mathbb{R}$, is $P_{n}(A)=\sum_{j=0}^{n} \alpha_{j} A^{j}$, $\mathfrak{D}\left(P_{n}(A)\right)=\mathfrak{D}\left(A^{n}\right)=\left\{\psi \in \mathfrak{D}(A) \mid A \psi \in \mathfrak{D}\left(A^{n-1}\right)\right\}\left(A^{0}=\mathbb{I}\right)$.

Axiom 3. The expectation value for a measurement of $a$, when the system is in the state $\psi \in \mathfrak{D}(A)$, is given by (2.5), which must be real for all $\psi \in \mathfrak{D}(A)$.

Axiom 4. The time evolution is given by a strongly continuous oneparameter unitary group $U(t)$. The generator of this group corresponds to the energy of the system.

In the following sections we will try to draw some mathematical consequences from these assumptions:

First we will see that Axioms 2 and 3 imply that observables correspond to self-adjoint operators. Hence these operators play a central role
in quantum mechanics and we will derive some of their basic properties. Another crucial role is played by the set of all possible expectation values for the measurement of $a$, which is connected with the spectrum $\sigma(A)$ of the corresponding operator $A$.

The problem of defining functions of an observable will lead us to the spectral theorem (in the next chapter), which generalizes the diagonalization of symmetric matrices.

Axiom 4 will be the topic of Chapter 5.

### 2.2. Self-adjoint operators

Let $\mathfrak{H}$ be a (complex separable) Hilbert space. A linear operator is a linear mapping

$$
\begin{equation*}
A: \mathfrak{D}(A) \rightarrow \mathfrak{H} \tag{2.13}
\end{equation*}
$$

where $\mathfrak{D}(A)$ is a linear subspace of $\mathfrak{H}$, called the domain of $A$. It is called bounded if the operator norm

$$
\begin{equation*}
\|A\|=\sup _{\|\psi\|=1}\|A \psi\|=\sup _{\|\varphi\|=\|\psi\|=1}|\langle\psi, A \varphi\rangle| \tag{2.14}
\end{equation*}
$$

is finite. The second equality follows since equality in $|\langle\psi, A \varphi\rangle| \leq\|\psi\|\|A \varphi\|$ is attained when $A \varphi=z \psi$ for some $z \in \mathbb{C}$. If $A$ is bounded, it is no restriction to assume $\mathfrak{D}(A)=\mathfrak{H}$ and we will always do so. The Banach space of all bounded linear operators is denoted by $\mathfrak{L}(\mathfrak{H})$. Products of (unbounded) operators are defined naturally; that is, $A B \psi=A(B \psi)$ for $\psi \in \mathfrak{D}(A B)=$ $\{\psi \in \mathfrak{D}(B) \mid B \psi \in \mathfrak{D}(A)\}$.

The expression $\langle\psi, A \psi\rangle$ encountered in the previous section is called the quadratic form,

$$
\begin{equation*}
q_{A}(\psi)=\langle\psi, A \psi\rangle, \quad \psi \in \mathfrak{D}(A), \tag{2.15}
\end{equation*}
$$

associated to $A$. An operator can be reconstructed from its quadratic form via the polarization identity

$$
\begin{equation*}
\langle\varphi, A \psi\rangle=\frac{1}{4}\left(q_{A}(\varphi+\psi)-q_{A}(\varphi-\psi)+\mathrm{i} q_{A}(\varphi-\mathrm{i} \psi)-\mathrm{i} q_{A}(\varphi+\mathrm{i} \psi)\right) . \tag{2.16}
\end{equation*}
$$

A densely defined linear operator $A$ is called symmetric (or hermitian) if

$$
\begin{equation*}
\langle\varphi, A \psi\rangle=\langle A \varphi, \psi\rangle, \quad \psi, \varphi \in \mathfrak{D}(A) . \tag{2.17}
\end{equation*}
$$

The justification for this definition is provided by the following
Lemma 2.1. A densely defined operator $A$ is symmetric if and only if the corresponding quadratic form is real-valued.

Proof. Clearly (2.17) implies that $\operatorname{Im}\left(q_{A}(\psi)\right)=0$. Conversely, taking the imaginary part of the identity

$$
q_{A}(\psi+\mathrm{i} \varphi)=q_{A}(\psi)+q_{A}(\varphi)+\mathrm{i}(\langle\psi, A \varphi\rangle-\langle\varphi, A \psi\rangle)
$$

shows $\operatorname{Re}\langle A \varphi, \psi\rangle=\operatorname{Re}\langle\varphi, A \psi\rangle$. Replacing $\varphi$ by $\mathrm{i} \varphi$ in this last equation shows $\operatorname{Im}\langle A \varphi, \psi\rangle=\operatorname{Im}\langle\varphi, A \psi\rangle$ and finishes the proof.

In other words, a densely defined operator $A$ is symmetric if and only if

$$
\begin{equation*}
\langle\psi, A \psi\rangle=\langle A \psi, \psi\rangle, \quad \psi \in \mathfrak{D}(A) . \tag{2.18}
\end{equation*}
$$

This already narrows the class of admissible operators to the class of symmetric operators by Axiom 3. Next, let us tackle the issue of the correct domain.

By Axiom 2, $A$ should be defined maximally; that is, if $\tilde{A}$ is another symmetric operator such that $A \subseteq \tilde{A}$, then $A=\tilde{A}$. Here we write $A \subseteq \tilde{A}$ if $\mathfrak{D}(A) \subseteq \mathfrak{D}(\tilde{A})$ and $A \psi=\tilde{A} \psi$ for all $\psi \in \mathfrak{D}(A)$. The operator $\tilde{A}$ is called an extension of $A$ in this case. In addition, we write $A=\tilde{A}$ if both $\tilde{A} \subseteq A$ and $A \subseteq \tilde{A}$ hold.

The adjoint operator $A^{*}$ of a densely defined linear operator $A$ is defined by

$$
\begin{align*}
\mathfrak{D}\left(A^{*}\right) & =\{\psi \in \mathfrak{H} \mid \exists \tilde{\psi} \in \mathfrak{H}:\langle\psi, A \varphi\rangle=\langle\tilde{\psi}, \varphi\rangle, \forall \varphi \in \mathfrak{D}(A)\},  \tag{2.19}\\
A^{*} \psi & =\tilde{\psi}
\end{align*}
$$

The requirement that $\mathfrak{D}(A)$ be dense implies that $A^{*}$ is well-defined. However, note that $\mathfrak{D}\left(A^{*}\right)$ might not be dense in general. In fact, it might contain no vectors other than 0 .

Clearly we have $(\alpha A)^{*}=\alpha^{*} A^{*}$ for $\alpha \in \mathbb{C}$ and $(A+B)^{*} \supseteq A^{*}+B^{*}$ provided $\mathfrak{D}(A+B)=\mathfrak{D}(A) \cap \mathfrak{D}(B)$ is dense. However, equality will not hold in general unless one operator is bounded (Problem 2.2).

For later use, note that (Problem 2.4)

$$
\begin{equation*}
\operatorname{Ker}\left(A^{*}\right)=\operatorname{Ran}(A)^{\perp} . \tag{2.20}
\end{equation*}
$$

For symmetric operators we clearly have $A \subseteq A^{*}$. If, in addition, $A=A^{*}$ holds, then $A$ is called self-adjoint. Our goal is to show that observables correspond to self-adjoint operators. This is for example true in the case of the position operator $x$, which is a special case of a multiplication operator.
Example. (Multiplication operator) Consider the multiplication operator

$$
\begin{equation*}
(A f)(x)=A(x) f(x), \quad \mathfrak{D}(A)=\left\{f \in L^{2}\left(\mathbb{R}^{n}, d \mu\right) \mid A f \in L^{2}\left(\mathbb{R}^{n}, d \mu\right)\right\} \tag{2.21}
\end{equation*}
$$

given by multiplication with the measurable function $A: \mathbb{R}^{n} \rightarrow \mathbb{C}$. First of all note that $\mathfrak{D}(A)$ is dense. In fact, consider $\Omega_{n}=\left\{x \in \mathbb{R}^{n}| | A(x) \mid \leq\right.$
$n\} \nearrow \mathbb{R}^{n}$. Then, for every $f \in L^{2}\left(\mathbb{R}^{n}, d \mu\right)$ the function $f_{n}=\chi_{\Omega_{n}} f \in \mathfrak{D}(A)$ converges to $f$ as $n \rightarrow \infty$ by dominated convergence.

Next, let us compute the adjoint of $A$. Performing a formal computation, we have for $h, f \in \mathfrak{D}(A)$ that

$$
\begin{equation*}
\langle h, A f\rangle=\int h(x)^{*} A(x) f(x) d \mu(x)=\int\left(A(x)^{*} h(x)\right)^{*} f(x) d \mu(x)=\langle\tilde{A} h, f\rangle \tag{2.22}
\end{equation*}
$$

where $\tilde{A}$ is multiplication by $A(x)^{*}$,

$$
\begin{equation*}
(\tilde{A} f)(x)=A(x)^{*} f(x), \quad \mathfrak{D}(\tilde{A})=\left\{f \in L^{2}\left(\mathbb{R}^{n}, d \mu\right) \mid \tilde{A} f \in L^{2}\left(\mathbb{R}^{n}, d \mu\right)\right\} \tag{2.23}
\end{equation*}
$$

Note $\mathfrak{D}(\tilde{A})=\mathfrak{D}(A)$. At first sight this seems to show that the adjoint of $A$ is $\tilde{A}$. But for our calculation we had to assume $h \in \mathfrak{D}(A)$ and there might be some functions in $\mathfrak{D}\left(A^{*}\right)$ which do not satisfy this requirement! In particular, our calculation only shows $\tilde{A} \subseteq A^{*}$. To show that equality holds, we need to work a little harder:

If $h \in \mathfrak{D}\left(A^{*}\right)$, there is some $g \in L^{2}\left(\mathbb{R}^{n}, d \mu\right)$ such that

$$
\begin{equation*}
\int h(x)^{*} A(x) f(x) d \mu(x)=\int g(x)^{*} f(x) d \mu(x), \quad f \in \mathfrak{D}(A), \tag{2.24}
\end{equation*}
$$

and thus

$$
\begin{equation*}
\int\left(h(x) A(x)^{*}-g(x)\right)^{*} f(x) d \mu(x)=0, \quad f \in \mathfrak{D}(A) . \tag{2.25}
\end{equation*}
$$

In particular,

$$
\begin{equation*}
\int \chi_{\Omega_{n}}(x)\left(h(x) A(x)^{*}-g(x)\right)^{*} f(x) d \mu(x)=0, \quad f \in L^{2}\left(\mathbb{R}^{n}, d \mu\right) \tag{2.26}
\end{equation*}
$$

which shows that $\chi_{\Omega_{n}}\left(h(x) A(x)^{*}-g(x)\right)^{*} \in L^{2}\left(\mathbb{R}^{n}, d \mu\right)$ vanishes. Since $n$ is arbitrary, we even have $h(x) A(x)^{*}=g(x) \in L^{2}\left(\mathbb{R}^{n}, d \mu\right)$ and thus $A^{*}$ is multiplication by $A(x)^{*}$ and $\mathfrak{D}\left(A^{*}\right)=\mathfrak{D}(A)$.

In particular, $A$ is self-adjoint if $A$ is real-valued. In the general case we have at least $\|A f\|=\left\|A^{*} f\right\|$ for all $f \in \mathfrak{D}(A)=\mathfrak{D}\left(A^{*}\right)$. Such operators are called normal.

Now note that

$$
\begin{equation*}
A \subseteq B \quad \Rightarrow \quad B^{*} \subseteq A^{*} \tag{2.27}
\end{equation*}
$$

that is, increasing the domain of $A$ implies decreasing the domain of $A^{*}$. Thus there is no point in trying to extend the domain of a self-adjoint operator further. In fact, if $A$ is self-adjoint and $B$ is a symmetric extension, we infer $A \subseteq B \subseteq B^{*} \subseteq A^{*}=A$ implying $A=B$.
Corollary 2.2. Self-adjoint operators are maximal; that is, they do not have any symmetric extensions.

Furthermore, if $A^{*}$ is densely defined (which is the case if $A$ is symmetric), we can consider $A^{* *}$. From the definition (2.19) it is clear that $A \subseteq A^{* *}$ and thus $A^{* *}$ is an extension of $A$. This extension is closely related to extending a linear subspace $M$ via $M^{\perp \perp}=\bar{M}$ (as we will see a bit later) and thus is called the closure $\bar{A}=A^{* *}$ of $A$.

If $A$ is symmetric, we have $A \subseteq A^{*}$ and hence $\bar{A}=A^{* *} \subseteq A^{*}$; that is, $\bar{A}$ lies between $A$ and $A^{*}$. Moreover, $\left\langle\psi, A^{*} \varphi\right\rangle=\langle\bar{A} \psi, \varphi\rangle$ for all $\psi \in \mathfrak{D}(\bar{A})$, $\varphi \in \mathfrak{D}\left(A^{*}\right)$ implies that $\bar{A}$ is symmetric since $A^{*} \varphi=\bar{A} \varphi$ for $\varphi \in \mathfrak{D}(\bar{A})$.
Example. (Differential operator) Take $\mathfrak{H}=L^{2}(0,2 \pi)$.
(i) Consider the operator

$$
\begin{equation*}
A_{0} f=-\mathrm{i} \frac{d}{d x} f, \quad \mathfrak{D}\left(A_{0}\right)=\left\{f \in C^{1}[0,2 \pi] \mid f(0)=f(2 \pi)=0\right\} . \tag{2.28}
\end{equation*}
$$

That $A_{0}$ is symmetric can be shown by a simple integration by parts (do this). Note that the boundary conditions $f(0)=f(2 \pi)=0$ are chosen such that the boundary terms occurring from integration by parts vanish. However, this will also follow once we have computed $A_{0}^{*}$. If $g \in \mathfrak{D}\left(A_{0}^{*}\right)$, we must have

$$
\begin{equation*}
\int_{0}^{2 \pi} g(x)^{*}\left(-\mathrm{i} f^{\prime}(x)\right) d x=\int_{0}^{2 \pi} \tilde{g}(x)^{*} f(x) d x \tag{2.29}
\end{equation*}
$$

for some $\tilde{g} \in L^{2}(0,2 \pi)$. Integration by parts (cf. (2.116)) shows

$$
\begin{equation*}
\int_{0}^{2 \pi} f^{\prime}(x)\left(g(x)-\mathrm{i} \int_{0}^{x} \tilde{g}(t) d t\right)^{*} d x=0 \tag{2.30}
\end{equation*}
$$

In fact, this formula holds for $\tilde{g} \in C[0,2 \pi]$. Since the set of continuous functions is dense, the general case $\tilde{g} \in L^{2}(0,2 \pi)$ follows by approximating $\tilde{g}$ with continuous functions and taking limits on both sides using dominated convergence.

Hence $g(x)-\mathrm{i} \int_{0}^{x} \tilde{g}(t) d t \in\left\{f^{\prime} \mid f \in \mathfrak{D}\left(A_{0}\right)\right\}^{\perp}$. But $\left\{f^{\prime} \mid f \in \mathfrak{D}\left(A_{0}\right)\right\}=$ $\left\{h \in C[0,2 \pi] \mid \int_{0}^{2 \pi} h(t) d t=0\right\}$ (show this) implying $g(x)=g(0)+\mathrm{i} \int_{0}^{x} \tilde{g}(t) d t$ since $\overline{\left\{f^{\prime} \mid f \in \mathfrak{D}\left(A_{0}\right)\right\}}=\{h \in \mathfrak{H} \mid\langle 1, h\rangle=0\}=\{1\}^{\perp}$ and $\{1\}^{\perp \perp}=\operatorname{span}\{1\}$. Thus $g \in A C[0,2 \pi]$, where

$$
\begin{equation*}
A C[a, b]=\left\{f \in C[a, b] \mid f(x)=f(a)+\int_{a}^{x} g(t) d t, g \in L^{1}(a, b)\right\} \tag{2.31}
\end{equation*}
$$

denotes the set of all absolutely continuous functions (see Section 2.7). In summary, $g \in \mathfrak{D}\left(A_{0}^{*}\right)$ implies $g \in A C[0,2 \pi]$ and $A_{0}^{*} g=\tilde{g}=-\mathrm{i} g^{\prime}$. Conversely, for every $g \in H^{1}(0,2 \pi)=\left\{f \in A C[0,2 \pi] \mid f^{\prime} \in L^{2}(0,2 \pi)\right\}$, (2.29) holds with $\tilde{g}=-\mathrm{i} g^{\prime}$ and we conclude

$$
\begin{equation*}
A_{0}^{*} f=-\mathrm{i} \frac{d}{d x} f, \quad \mathfrak{D}\left(A_{0}^{*}\right)=H^{1}(0,2 \pi) . \tag{2.32}
\end{equation*}
$$

In particular, $A_{0}$ is symmetric but not self-adjoint. Since $\overline{A_{0}}=A_{0}^{* *} \subseteq A_{0}^{*}$, we can use integration by parts to compute

$$
\begin{equation*}
0=\left\langle g, \overline{A_{0}} f\right\rangle-\left\langle A_{0}^{*} g, f\right\rangle=\mathrm{i}\left(f(0) g(0)^{*}-f(2 \pi) g(2 \pi)^{*}\right) \tag{2.33}
\end{equation*}
$$

and since the boundary values of $g \in \mathfrak{D}\left(A_{0}^{*}\right)$ can be prescribed arbitrarily, we must have $f(0)=f(2 \pi)=0$. Thus

$$
\begin{equation*}
\overline{A_{0}} f=-\mathrm{i} \frac{d}{d x} f, \quad \mathfrak{D}\left(\overline{A_{0}}\right)=\left\{f \in \mathfrak{D}\left(A_{0}^{*}\right) \mid f(0)=f(2 \pi)=0\right\} . \tag{2.34}
\end{equation*}
$$

(ii) Now let us take

$$
\begin{equation*}
A f=-\mathrm{i} \frac{d}{d x} f, \quad \mathfrak{D}(A)=\left\{f \in C^{1}[0,2 \pi] \mid f(0)=f(2 \pi)\right\} \tag{2.35}
\end{equation*}
$$

which is clearly an extension of $A_{0}$. Thus $A^{*} \subseteq A_{0}^{*}$ and we compute

$$
\begin{equation*}
0=\langle g, A f\rangle-\left\langle A^{*} g, f\right\rangle=\mathrm{i} f(0)\left(g(0)^{*}-g(2 \pi)^{*}\right) \tag{2.36}
\end{equation*}
$$

Since this must hold for all $f \in \mathfrak{D}(A)$, we conclude $g(0)=g(2 \pi)$ and

$$
\begin{equation*}
A^{*} f=-\mathrm{i} \frac{d}{d x} f, \quad \mathfrak{D}\left(A^{*}\right)=\left\{f \in H^{1}(0,2 \pi) \mid f(0)=f(2 \pi)\right\} . \tag{2.37}
\end{equation*}
$$

Similarly, as before, $\bar{A}=A^{*}$ and thus $\bar{A}$ is self-adjoint.
One might suspect that there is no big difference between the two symmetric operators $A_{0}$ and $A$ from the previous example, since they coincide on a dense set of vectors. However, the converse is true: For example, the first operator $A_{0}$ has no eigenvectors at all (i.e., solutions of the equation $A_{0} \psi=z \psi, z \in \mathbb{C}$ ) whereas the second one has an orthonormal basis of eigenvectors!
Example. Compute the eigenvectors of $A_{0}$ and $A$ from the previous example.
(i) By definition, an eigenvector is a (nonzero) solution of $A_{0} u=z u$, $z \in \mathbb{C}$, that is, a solution of the ordinary differential equation

$$
\begin{equation*}
-\mathrm{i} u^{\prime}(x)=z u(x) \tag{2.38}
\end{equation*}
$$

satisfying the boundary conditions $u(0)=u(2 \pi)=0$ (since we must have $u \in \mathfrak{D}\left(A_{0}\right)$ ). The general solution of the differential equation is $u(x)=$ $u(0) \mathrm{e}^{\mathrm{i} z x}$ and the boundary conditions imply $u(x)=0$. Hence there are no eigenvectors.
(ii) Now we look for solutions of $A u=z u$, that is, the same differential equation as before, but now subject to the boundary condition $u(0)=u(2 \pi)$. Again the general solution is $u(x)=u(0) \mathrm{e}^{\mathrm{i} z x}$ and the boundary condition requires $u(0)=u(0) \mathrm{e}^{2 \pi \mathrm{i} z}$. Thus there are two possibilities. Either $u(0)=0$
(which is of no use for us) or $z \in \mathbb{Z}$. In particular, we see that all eigenvectors are given by

$$
\begin{equation*}
u_{n}(x)=\frac{1}{\sqrt{2 \pi}} \mathrm{e}^{\mathrm{i} n x}, \quad n \in \mathbb{Z} \tag{2.39}
\end{equation*}
$$

which are well known to form an orthonormal basis.
We will see a bit later that this is a consequence of self-adjointness of $\bar{A}$. Hence it will be important to know whether a given operator is selfadjoint or not. Our example shows that symmetry is easy to check (in case of differential operators it usually boils down to integration by parts), but computing the adjoint of an operator is a nontrivial job even in simple situations. However, we will learn soon that self-adjointness is a much stronger property than symmetry, justifying the additional effort needed to prove it.

On the other hand, if a given symmetric operator $A$ turns out not to be self-adjoint, this raises the question of self-adjoint extensions. Two cases need to be distinguished. If $\bar{A}$ is self-adjoint, then there is only one selfadjoint extension (if $B$ is another one, we have $\bar{A} \subseteq B$ and hence $\bar{A}=B$ by Corollary 2.2). In this case $A$ is called essentially self-adjoint and $\mathfrak{D}(A)$ is called a core for $\bar{A}$. Otherwise there might be more than one selfadjoint extension or none at all. This situation is more delicate and will be investigated in Section 2.6.

Since we have seen that computing $A^{*}$ is not always easy, a criterion for self-adjointness not involving $A^{*}$ will be useful.

Lemma 2.3. Let $A$ be symmetric such that $\operatorname{Ran}(A+z)=\operatorname{Ran}\left(A+z^{*}\right)=\mathfrak{H}$ for one $z \in \mathbb{C}$. Then $A$ is self-adjoint.

Proof. Let $\psi \in \mathfrak{D}\left(A^{*}\right)$ and $A^{*} \psi=\tilde{\psi}$. Since $\operatorname{Ran}\left(A+z^{*}\right)=\mathfrak{H}$, there is a $\vartheta \in \mathfrak{D}(A)$ such that $\left(A+z^{*}\right) \vartheta=\tilde{\psi}+z^{*} \psi$. Now we compute
$\langle\psi,(A+z) \varphi\rangle=\left\langle\tilde{\psi}+z^{*} \psi, \varphi\right\rangle=\left\langle\left(A+z^{*}\right) \vartheta, \varphi\right\rangle=\langle\vartheta,(A+z) \varphi\rangle, \quad \varphi \in \mathfrak{D}(A)$, and hence $\psi=\vartheta \in \mathfrak{D}(A)$ since $\operatorname{Ran}(A+z)=\mathfrak{H}$.

To proceed further, we will need more information on the closure of an operator. We will use a different approach which avoids the use of the adjoint operator. We will establish equivalence with our original definition in Lemma 2.4.

The simplest way of extending an operator $A$ is to take the closure of its graph $\Gamma(A)=\{(\psi, A \psi) \mid \psi \in \mathfrak{D}(A)\} \subset \mathfrak{H}^{2}$. That is, if $\left(\psi_{n}, A \psi_{n}\right) \rightarrow(\psi, \tilde{\psi})$, we might try to define $A \psi=\tilde{\sim}$. For $A \psi$ to be well-defined, we need that $\left(\psi_{n}, A \psi_{n}\right) \rightarrow(0, \tilde{\psi})$ implies $\tilde{\psi}=0$. In this case $A$ is called closable and the unique operator $\bar{A}$ which satisfies $\Gamma(\bar{A})=\overline{\Gamma(A)}$ is called the closure of $A$. Clearly, $A$ is called closed if $\bar{A}=A$, which is the case if and only if the
graph of $A$ is closed. Equivalently, $A$ is closed if and only if $\Gamma(A)$ equipped with the graph norm $\|(\psi, A \psi)\|_{\Gamma(A)}^{2}=\|\psi\|^{2}+\|A \psi\|^{2}$ is a Hilbert space (i.e., closed). By construction, $\bar{A}$ is the smallest closed extension of $A$.

Example. Suppose $A$ is bounded. Then the closure was already computed in Theorem 0.26 . In particular, $\mathfrak{D}(\bar{A})=\overline{\mathfrak{D}(A)}$ and a bounded operator is closed if and only if its domain is closed.

Example. Consider again the differential operator $A_{0}$ from (2.28) and let us compute the closure without the use of the adjoint operator.

Let $f \in \mathfrak{D}\left(\overline{A_{0}}\right)$ and let $f_{n} \in \mathfrak{D}\left(A_{0}\right)$ be a sequence such that $f_{n} \rightarrow f$, $A_{0} f_{n} \rightarrow-\mathrm{i} g$. Then $f_{n}^{\prime} \rightarrow g$ and hence $f(x)=\int_{0}^{x} g(t) d t$. Thus $f \in A C[0,2 \pi]$ and $f(0)=0$. Moreover $f(2 \pi)=\lim _{n \rightarrow 0} \int_{0}^{2 \pi} f_{n}^{\prime}(t) d t=0$. Conversely, any such $f$ can be approximated by functions in $\mathfrak{D}\left(A_{0}\right)$ (show this).

Example. Consider again the multiplication operator by $A(x)$ in $L^{2}\left(\mathbb{R}^{n}, d \mu\right)$ but now defined on functions with compact support, that is,

$$
\begin{equation*}
\mathfrak{D}\left(A_{0}\right)=\{f \in \mathfrak{D}(A) \mid \operatorname{supp}(f) \text { is compact }\} \tag{2.40}
\end{equation*}
$$

Then its closure is given by $\overline{A_{0}}=A$. In particular, $A_{0}$ is essentially selfadjoint and $\mathfrak{D}\left(A_{0}\right)$ is a core for $A$.

To prove $\overline{A_{0}}=A$, let some $f \in \mathfrak{D}(A)$ be given and consider $f_{n}=$ $\chi_{\{x| | x \mid \leq n\}} f$. Then $f_{n} \in \mathfrak{D}\left(A_{0}\right)$ and $f_{n}(x) \rightarrow f(x)$ as well as $A(x) f_{n}(x) \rightarrow$ $A(x) f(x)$ in $L^{2}\left(\mathbb{R}^{n}, d \mu\right)$ by dominated convergence. Thus $\mathfrak{D}\left(\overline{A_{0}}\right) \subseteq \mathfrak{D}(A)$ and since $A$ is closed, we even get equality.

Example. Consider the multiplication $A(x)=x$ in $L^{2}(\mathbb{R})$ defined on

$$
\begin{equation*}
\mathfrak{D}\left(A_{0}\right)=\left\{f \in \mathfrak{D}(A) \mid \int_{\mathbb{R}} f(x) d x=0\right\} \tag{2.41}
\end{equation*}
$$

Then $A_{0}$ is closed. Hence $\mathfrak{D}\left(A_{0}\right)$ is not a core for $A$.
To show that $A_{0}$ is closed, suppose there is a sequence $f_{n}(x) \rightarrow f(x)$ such that $x f_{n}(x) \rightarrow g(x)$. Since $A$ is closed, we necessarily have $f \in \mathfrak{D}(A)$ and $g(x)=x f(x)$. But then

$$
\begin{align*}
0 & =\lim _{n \rightarrow \infty} \int_{\mathbb{R}} f_{n}(x) d x=\lim _{n \rightarrow \infty} \int_{\mathbb{R}} \frac{1}{1+|x|}\left(f_{n}(x)+\operatorname{sign}(x) x f_{n}(x)\right) d x \\
& =\int_{\mathbb{R}} \frac{1}{1+|x|}(f(x)+\operatorname{sign}(x) g(x)) d x=\int_{\mathbb{R}} f(x) d x \tag{2.42}
\end{align*}
$$

which shows $f \in \mathfrak{D}\left(A_{0}\right)$.
Next, let us collect a few important results.

Lemma 2.4. Suppose $A$ is a densely defined operator.
(i) $A^{*}$ is closed.
(ii) $A$ is closable if and only if $\mathfrak{D}\left(A^{*}\right)$ is dense and $\bar{A}=A^{* *}$, respectively, $(\bar{A})^{*}=A^{*}$, in this case.
(iii) If $A$ is injective and $\operatorname{Ran}(A)$ is dense, then $\left(A^{*}\right)^{-1}=\left(A^{-1}\right)^{*}$. If $A$ is closable and $\bar{A}$ is injective, then $\bar{A}^{-1}=\overline{A^{-1}}$.

Proof. Let us consider the following two unitary operators from $\mathfrak{H}^{2}$ to itself

$$
U(\varphi, \psi)=(\psi,-\varphi), \quad V(\varphi, \psi)=(\psi, \varphi) .
$$

(i) From

$$
\begin{align*}
\Gamma\left(A^{*}\right) & =\left\{(\varphi, \tilde{\varphi}) \in \mathfrak{H}^{2} \mid\langle\varphi, A \psi\rangle=\langle\tilde{\varphi}, \psi\rangle, \forall \psi \in \mathfrak{D}(A)\right\} \\
& =\left\{(\varphi, \tilde{\varphi}) \in \mathfrak{H}^{2} \mid\langle(\varphi, \tilde{\varphi}),(\tilde{\psi},-\psi)\rangle_{\mathfrak{H}^{2}}=0, \forall(\psi, \tilde{\psi}) \in \Gamma(A)\right\} \\
& =(U \Gamma(A))^{\perp} \tag{2.43}
\end{align*}
$$

we conclude that $A^{*}$ is closed.
(ii) Similarly, using $U \Gamma^{\perp}=(U \Gamma)^{\perp}$ (Problem 1.4), by

$$
\begin{aligned}
\overline{\Gamma(A)} & =\Gamma(A)^{\perp \perp}=\left(U \Gamma\left(A^{*}\right)\right)^{\perp} \\
& =\left\{(\psi, \tilde{\psi}) \mid\left\langle\psi, A^{*} \varphi\right\rangle-\langle\tilde{\psi}, \varphi\rangle=0, \forall \varphi \in \mathfrak{D}\left(A^{*}\right)\right\}
\end{aligned}
$$

we see that $(0, \tilde{\psi}) \in \overline{\Gamma(A)}$ if and only if $\tilde{\psi} \in \mathfrak{D}\left(A^{*}\right)^{\perp}$. Hence $A$ is closable if and only if $\mathfrak{D}\left(A^{*}\right)$ is dense. In this case, equation (2.43) also shows $\bar{A}^{*}=A^{*}$. Moreover, replacing $A$ by $A^{*}$ in (2.43) and comparing with the last formula shows $A^{* *}=\bar{A}$.
(iii) Next note that (provided $A$ is injective)

$$
\Gamma\left(A^{-1}\right)=V \Gamma(A) .
$$

Hence if $\operatorname{Ran}(A)$ is dense, then $\operatorname{Ker}\left(A^{*}\right)=\operatorname{Ran}(A)^{\perp}=\{0\}$ and

$$
\Gamma\left(\left(A^{*}\right)^{-1}\right)=V \Gamma\left(A^{*}\right)=V U \Gamma(A)^{\perp}=U V \Gamma(A)^{\perp}=U(V \Gamma(A))^{\perp}
$$

shows that $\left(A^{*}\right)^{-1}=\left(A^{-1}\right)^{*}$. Similarly, if $A$ is closable and $\bar{A}$ is injective, then $\bar{A}^{-1}=\overline{A^{-1}}$ by

$$
\Gamma\left(\bar{A}^{-1}\right)=V \Gamma(\bar{A})=\overline{V \Gamma(A)}=\Gamma\left(\overline{A^{-1}}\right) .
$$

Corollary 2.5. If $A$ is self-adjoint and injective, then $A^{-1}$ is also selfadjoint.

Proof. Equation (2.20) in the case $A=A^{*}$ implies $\operatorname{Ran}(A)^{\perp}=\operatorname{Ker}(A)=$ $\{0\}$ and hence (iii) is applicable.

If $A$ is densely defined and bounded, we clearly have $\mathfrak{D}\left(A^{*}\right)=\mathfrak{H}$ and by Corollary 1.9, $A^{*} \in \mathfrak{L}(\mathfrak{H})$. In particular, since $\bar{A}=A^{* *}$, we obtain

Theorem 2.6. We have $\bar{A} \in \mathfrak{L}(\mathfrak{H})$ if and only if $A^{*} \in \mathfrak{L}(\mathfrak{H})$.
Now we can also generalize Lemma 2.3 to the case of essential self-adjoint operators.

Lemma 2.7. A symmetric operator $A$ is essentially self-adjoint if and only if one of the following conditions holds for one $z \in \mathbb{C} \backslash \mathbb{R}$ :

- $\overline{\operatorname{Ran}(A+z)}=\overline{\operatorname{Ran}\left(A+z^{*}\right)}=\mathfrak{H}$,
- $\operatorname{Ker}\left(A^{*}+z\right)=\operatorname{Ker}\left(A^{*}+z^{*}\right)=\{0\}$.

If $A$ is nonnegative, that is, $\langle\psi, A \psi\rangle \geq 0$ for all $\psi \in \mathfrak{D}(A)$, we can also admit $z \in(-\infty, 0)$.

Proof. First of all note that by (2.20) the two conditions are equivalent. By taking the closure of $A$, it is no restriction to assume that $A$ is closed. Let $z=x+\mathrm{i} y$. From

$$
\begin{align*}
\|(A+z) \psi\|^{2} & =\|(A+x) \psi+\mathrm{i} y \psi\|^{2} \\
& =\|(A+x) \psi\|^{2}+y^{2}\|\psi\|^{2} \geq y^{2}\|\psi\|^{2} \tag{2.44}
\end{align*}
$$

we infer that $\operatorname{Ker}(A+z)=\{0\}$ and hence $(A+z)^{-1}$ exists. Moreover, setting $\psi=(A+z)^{-1} \varphi(y \neq 0)$ shows $\left\|(A+z)^{-1}\right\| \leq|y|^{-1}$. Hence $(A+z)^{-1}$ is bounded and closed. Since it is densely defined by assumption, its domain $\operatorname{Ran}(A+z)$ must be equal to $\mathfrak{H}$. Replacing $z$ by $z^{*}$, we see $\operatorname{Ran}\left(A+z^{*}\right)=\mathfrak{H}$ and applying Lemma 2.3 shows that $A$ is self-adjoint. Conversely, if $A=A^{*}$, the above calculation shows $\operatorname{Ker}\left(A^{*}+z\right)=\{0\}$, which finishes the case $z \in \mathbb{C} \backslash \mathbb{R}$.

The argument for the nonnegative case with $z<0$ is similar using $\varepsilon\|\psi\|^{2} \leq\langle\psi,(A+\varepsilon) \psi\rangle \leq\|\psi\|\|(A+\varepsilon) \psi\|$ which shows $(A+\varepsilon)^{-1} \leq \varepsilon^{-1}$, $\varepsilon>0$.

In addition, we can also prove the closed graph theorem which shows that an unbounded closed operator cannot be defined on the entire Hilbert space.

Theorem 2.8 (Closed graph). Let $\mathfrak{H}_{1}$ and $\mathfrak{H}_{2}$ be two Hilbert spaces and $A: \mathfrak{H}_{1} \rightarrow \mathfrak{H}_{2}$ an operator defined on all of $\mathfrak{H}_{1}$. Then $A$ is bounded if and only if $\Gamma(A)$ is closed.

Proof. If $A$ is bounded, then it is easy to see that $\Gamma(A)$ is closed. So let us assume that $\Gamma(A)$ is closed. Then $A^{*}$ is well-defined and for all unit vectors
$\varphi \in \mathfrak{D}\left(A^{*}\right)$ we have that the linear functional $\ell_{\varphi}(\psi)=\left\langle A^{*} \varphi, \psi\right\rangle$ is pointwise bounded, that is,

$$
\left\|\ell_{\varphi}(\psi)\right\|=|\langle\varphi, A \psi\rangle| \leq\|A \psi\| .
$$

Hence by the uniform boundedness principle there is a constant $C$ such that $\left\|\ell_{\varphi}\right\|=\left\|A^{*} \varphi\right\| \leq C$. That is, $A^{*}$ is bounded and so is $A=A^{* *}$.

Note that since symmetric operators are closable, they are automatically closed if they are defined on the entire Hilbert space.

Theorem 2.9 (Hellinger-Toeplitz). A symmetric operator defined on the entire Hilbert space is bounded.

Problem 2.1 (Jacobi operator). Let $a$ and $b$ be some real-valued sequences in $\ell^{\infty}(\mathbb{Z})$. Consider the operator

$$
J f_{n}=a_{n} f_{n+1}+a_{n-1} f_{n-1}+b_{n} f_{n}, \quad f \in \ell^{2}(\mathbb{Z}) .
$$

Show that $J$ is a bounded self-adjoint operator.
Problem 2.2. Show that $(\alpha A)^{*}=\alpha^{*} A^{*}$ and $(A+B)^{*} \supseteq A^{*}+B^{*}$ (where $\left.\mathfrak{D}\left(A^{*}+B^{*}\right)=\mathfrak{D}\left(A^{*}\right) \cap \mathfrak{D}\left(B^{*}\right)\right)$ with equality if one operator is bounded. Give an example where equality does not hold.

Problem 2.3. Suppose $A B$ is densely defined. Show that $(A B)^{*} \supseteq B^{*} A^{*}$. Moreover, if $B$ is bounded, then $(B A)^{*}=A^{*} B^{*}$.

Problem 2.4. Show (2.20).
Problem 2.5. An operator is called normal if $\|A \psi\|=\left\|A^{*} \psi\right\|$ for all $\psi \in \mathfrak{D}(A)=\mathfrak{D}\left(A^{*}\right)$.

Show that if $A$ is normal, so is $A+z$ for any $z \in \mathbb{C}$.
Problem 2.6. Show that normal operators are closed. (Hint: $A^{*}$ is closed.)
Problem 2.7. Show that a bounded operator $A$ is normal if and only if $A A^{*}=A^{*} A$.

Problem 2.8. Show that the kernel of a closed operator is closed.
Problem 2.9. Show that if $A$ is closed and $B$ bounded, then $A B$ is closed.

### 2.3. Quadratic forms and the Friedrichs extension

Finally we want to draw some further consequences of Axiom 2 and show that observables correspond to self-adjoint operators. Since self-adjoint operators are already maximal, the difficult part remaining is to show that an observable has at least one self-adjoint extension. There is a good way of doing this for nonnegative operators and hence we will consider this case first.

An operator is called nonnegative (resp. positive) if $\langle\psi, A \psi\rangle \geq 0$ (resp. $>0$ for $\psi \neq 0$ ) for all $\psi \in \mathfrak{D}(A)$. If $A$ is positive, the map $(\varphi, \psi) \mapsto\langle\varphi, A \psi\rangle$ is a scalar product. However, there might be sequences which are Cauchy with respect to this scalar product but not with respect to our original one. To avoid this, we introduce the scalar product

$$
\begin{equation*}
\langle\varphi, \psi\rangle_{A}=\langle\varphi,(A+1) \psi\rangle, \quad A \geq 0, \tag{2.45}
\end{equation*}
$$

defined on $\mathfrak{D}(A)$, which satisfies $\|\psi\| \leq\|\psi\|_{A}$. Let $\mathfrak{H}_{A}$ be the completion of $\mathfrak{D}(A)$ with respect to the above scalar product. We claim that $\mathfrak{H}_{A}$ can be regarded as a subspace of $\mathfrak{H}$; that is, $\mathfrak{D}(A) \subseteq \mathfrak{H}_{A} \subseteq \mathfrak{H}$.

If $\left(\psi_{n}\right)$ is a Cauchy sequence in $\mathfrak{D}(A)$, then it is also Cauchy in $\mathfrak{H}$ (since $\|\psi\| \leq\|\psi\|_{A}$ by assumption) and hence we can identify the limit in $\mathfrak{H}_{A}$ with the limit of $\left(\psi_{n}\right)$ regarded as a sequence in $\mathfrak{H}$. For this identification to be unique, we need to show that if $\left(\psi_{n}\right) \subset \mathfrak{D}(A)$ is a Cauchy sequence in $\mathfrak{H}_{A}$ such that $\left\|\psi_{n}\right\| \rightarrow 0$, then $\left\|\psi_{n}\right\|_{A} \rightarrow 0$. This follows from

$$
\begin{align*}
\left\|\psi_{n}\right\|_{A}^{2} & =\left\langle\psi_{n}, \psi_{n}-\psi_{m}\right\rangle_{A}+\left\langle\psi_{n}, \psi_{m}\right\rangle_{A} \\
& \leq\left\|\psi_{n}\right\|_{A}\left\|\psi_{n}-\psi_{m}\right\|_{A}+\left\|\psi_{n}\right\|\left\|(A+1) \psi_{m}\right\| \tag{2.46}
\end{align*}
$$

since the right-hand side can be made arbitrarily small choosing $m, n$ large.
Clearly the quadratic form $q_{A}$ can be extended to every $\psi \in \mathfrak{H}_{A}$ by setting

$$
\begin{equation*}
q_{A}(\psi)=\langle\psi, \psi\rangle_{A}-\|\psi\|^{2}, \quad \psi \in \mathfrak{Q}(A)=\mathfrak{H}_{A} . \tag{2.47}
\end{equation*}
$$

The set $\mathfrak{Q}(A)$ is also called the form domain of $A$.
Example. (Multiplication operator) Let $A$ be multiplication by $A(x) \geq 0$ in $L^{2}\left(\mathbb{R}^{n}, d \mu\right)$. Then

$$
\begin{equation*}
\mathfrak{Q}(A)=\mathfrak{D}\left(A^{1 / 2}\right)=\left\{f \in L^{2}\left(\mathbb{R}^{n}, d \mu\right) \mid A^{1 / 2} f \in L^{2}\left(\mathbb{R}^{n}, d \mu\right)\right\} \tag{2.48}
\end{equation*}
$$

and

$$
\begin{equation*}
q_{A}(x)=\int_{\mathbb{R}^{n}} A(x)|f(x)|^{2} d \mu(x) \tag{2.49}
\end{equation*}
$$

(show this).
Now we come to our extension result. Note that $A+1$ is injective and the best we can hope for is that for a nonnegative extension $\tilde{A}$, the operator $\tilde{A}+1$ is a bijection from $\mathfrak{D}(\tilde{A})$ onto $\mathfrak{H}$.

Lemma 2.10. Suppose $A$ is a nonnegative operator. Then there is a nonnegative extension $\tilde{A}$ such that $\operatorname{Ran}(\tilde{A}+1)=\mathfrak{H}$.

Proof. Let us define an operator $\tilde{A}$ by

$$
\begin{aligned}
\mathfrak{D}(\tilde{A}) & =\left\{\psi \in \mathfrak{H}_{A} \mid \exists \tilde{\psi} \in \mathfrak{H}:\langle\varphi, \psi\rangle_{A}=\langle\varphi, \tilde{\psi}\rangle, \forall \varphi \in \mathfrak{H}_{A}\right\} \\
\tilde{A} \psi & =\tilde{\psi}-\psi .
\end{aligned}
$$

Since $\mathfrak{H}_{A}$ is dense, $\tilde{\psi}$ is well-defined. Moreover, it is straightforward to see that $\tilde{A}$ is a nonnegative extension of $A$.

It is also not hard to see that $\operatorname{Ran}(\tilde{A}+1)=\mathfrak{H}$. Indeed, for any $\tilde{\psi} \in \mathfrak{H}$, $\varphi \mapsto\langle\tilde{\psi}, \varphi\rangle$ is a bounded linear functional on $\mathfrak{H}_{A}$. Hence there is an element $\psi \in \mathfrak{H}_{A}$ such that $\langle\tilde{\psi}, \varphi\rangle=\langle\psi, \varphi\rangle_{A}$ for all $\varphi \in \mathfrak{H}_{A}$. By the definition of $\tilde{A}$, $(\tilde{A}+1) \psi=\tilde{\psi}$ and hence $\tilde{A}+1$ is onto.

Example. Let us take $\mathfrak{H}=L^{2}(0, \pi)$ and consider the operator

$$
\begin{equation*}
A f=-\frac{d^{2}}{d x^{2}} f, \quad \mathfrak{D}(A)=\left\{f \in C^{2}[0, \pi] \mid f(0)=f(\pi)=0\right\} \tag{2.50}
\end{equation*}
$$

which corresponds to the one-dimensional model of a particle confined to a box.
(i) First of all, using integration by parts twice, it is straightforward to check that $A$ is symmetric:

$$
\begin{equation*}
\int_{0}^{\pi} g(x)^{*}\left(-f^{\prime \prime}\right)(x) d x=\int_{0}^{\pi} g^{\prime}(x)^{*} f^{\prime}(x) d x=\int_{0}^{\pi}\left(-g^{\prime \prime}\right)(x)^{*} f(x) d x \tag{2.51}
\end{equation*}
$$

Note that the boundary conditions $f(0)=f(\pi)=0$ are chosen such that the boundary terms occurring from integration by parts vanish. Moreover, the same calculation also shows that $A$ is positive:

$$
\begin{equation*}
\int_{0}^{\pi} f(x)^{*}\left(-f^{\prime \prime}\right)(x) d x=\int_{0}^{\pi}\left|f^{\prime}(x)\right|^{2} d x>0, \quad f \neq 0 \tag{2.52}
\end{equation*}
$$

(ii) Next let us show $\mathfrak{H}_{A}=\left\{f \in H^{1}(0, \pi) \mid f(0)=f(\pi)=0\right\}$. In fact, since

$$
\begin{equation*}
\langle g, f\rangle_{A}=\int_{0}^{\pi}\left(g^{\prime}(x)^{*} f^{\prime}(x)+g(x)^{*} f(x)\right) d x \tag{2.53}
\end{equation*}
$$

we see that $f_{n}$ is Cauchy in $\mathfrak{H}_{A}$ if and only if both $f_{n}$ and $f_{n}^{\prime}$ are Cauchy in $L^{2}(0, \pi)$. Thus $f_{n} \rightarrow f$ and $f_{n}^{\prime} \rightarrow g$ in $L^{2}(0, \pi)$ and $f_{n}(x)=\int_{0}^{x} f_{n}^{\prime}(t) d t$ implies $f(x)=\int_{0}^{x} g(t) d t$. Thus $f \in A C[0, \pi]$. Moreover, $f(0)=0$ is obvious and from $0=f_{n}(\pi)=\int_{0}^{\pi} f_{n}^{\prime}(t) d t$ we have $f(\pi)=\lim _{n \rightarrow \infty} \int_{0}^{\pi} f_{n}^{\prime}(t) d t=0$. So we have $\mathfrak{H}_{A} \subseteq\left\{f \in H^{1}(0, \pi) \mid f(0)=f(\pi)=0\right\}$. To see the converse, approximate $f^{\prime}$ by smooth functions $g_{n}$. Using $g_{n}-\frac{1}{\pi} \int_{0}^{\pi} g_{n}(t) d t$ instead of $g_{n}$, it is no restriction to assume $\int_{0}^{\pi} g_{n}(t) d t=0$. Now define $f_{n}(x)=$ $\int_{0}^{x} g_{n}(t) d t$ and note $f_{n} \in \mathfrak{D}(A) \rightarrow f$.
(iii) Finally, let us compute the extension $\tilde{A}$. We have $f \in \mathfrak{D}(\tilde{A})$ if for all $g \in \mathfrak{H}_{A}$ there is an $\tilde{f}$ such that $\langle g, f\rangle_{A}=\langle g, \tilde{f}\rangle$. That is,

$$
\begin{equation*}
\int_{0}^{\pi} g^{\prime}(x)^{*} f^{\prime}(x) d x=\int_{0}^{\pi} g(x)^{*}(\tilde{f}(x)-f(x)) d x \tag{2.54}
\end{equation*}
$$

Integration by parts on the right-hand side shows

$$
\begin{equation*}
\int_{0}^{\pi} g^{\prime}(x)^{*} f^{\prime}(x) d x=-\int_{0}^{\pi} g^{\prime}(x)^{*} \int_{0}^{x}(\tilde{f}(t)-f(t)) d t d x \tag{2.55}
\end{equation*}
$$

or equivalently

$$
\begin{equation*}
\int_{0}^{\pi} g^{\prime}(x)^{*}\left(f^{\prime}(x)+\int_{0}^{x}(\tilde{f}(t)-f(t)) d t\right) d x=0 \tag{2.56}
\end{equation*}
$$

Now observe $\left\{g^{\prime} \in \mathfrak{H} \mid g \in \mathfrak{H}_{A}\right\}=\left\{h \in \mathfrak{H} \mid \int_{0}^{\pi} h(t) d t=0\right\}=\{1\}^{\perp}$ and thus $f^{\prime}(x)+\int_{0}^{x}(\tilde{f}(t)-f(t)) d t \in\{1\}^{\perp \perp}=\operatorname{span}\{1\}$. So we see $f \in H^{2}(0, \pi)=$ $\left\{f \in A C[0, \pi] \mid f^{\prime} \in H^{1}(0, \pi)\right\}$ and $\tilde{A} f=-f^{\prime \prime}$. The converse is easy and hence

$$
\begin{equation*}
\tilde{A} f=-\frac{d^{2}}{d x^{2}} f, \quad \mathfrak{D}(\tilde{A})=\left\{f \in H^{2}[0, \pi] \mid f(0)=f(\pi)=0\right\} . \tag{2.57}
\end{equation*}
$$

Now let us apply this result to operators $A$ corresponding to observables. Since $A$ will, in general, not satisfy the assumptions of our lemma, we will consider $A^{2}$ instead, which has a symmetric extension $\tilde{A}^{2}$ with $\operatorname{Ran}\left(\tilde{A}^{2}+1\right)=$ $\mathfrak{H}$. By our requirement for observables, $A^{2}$ is maximally defined and hence is equal to this extension. In other words, $\operatorname{Ran}\left(A^{2}+1\right)=\mathfrak{H}$. Moreover, for any $\varphi \in \mathfrak{H}$ there is a $\psi \in \mathfrak{D}\left(A^{2}\right)$ such that

$$
\begin{equation*}
(A-\mathrm{i})(A+\mathrm{i}) \psi=(A+\mathrm{i})(A-\mathrm{i}) \psi=\varphi \tag{2.58}
\end{equation*}
$$

and since $(A \pm \mathrm{i}) \psi \in \mathfrak{D}(A)$, we infer $\operatorname{Ran}(A \pm \mathrm{i})=\mathfrak{H}$. As an immediate consequence we obtain
Corollary 2.11. Observables correspond to self-adjoint operators.
But there is another important consequence of the results which is worthwhile mentioning. A symmetric operator is called semi-bounded, respectively, bounded from below, if

$$
\begin{equation*}
q_{A}(\psi)=\langle\psi, A \psi\rangle \geq \gamma\|\psi\|^{2}, \quad \gamma \in \mathbb{R} \tag{2.59}
\end{equation*}
$$

We will write $A \geq \gamma$ for short.
Theorem 2.12 (Friedrichs extension). Let A be a symmetric operator which is bounded from below by $\gamma$. Then there is a self-adjoint extension $\tilde{A}$ which is also bounded from below by $\gamma$ and which satisfies $\mathfrak{D}(\tilde{A}) \subseteq \mathfrak{H}_{A-\gamma}$.

Moreover, $\tilde{A}$ is the only self-adjoint extension with $\mathfrak{D}(\tilde{A}) \subseteq \mathfrak{H}_{A-\gamma}$.
Proof. If we replace $A$ by $A-\gamma$, then existence follows from Lemma 2.10. To see uniqueness, let $\hat{A}$ be another self-adjoint extension with $\mathfrak{D}(\hat{A}) \subseteq \mathfrak{H}_{A}$. Choose $\varphi \in \mathfrak{D}(A)$ and $\psi \in \mathfrak{D}(\hat{A})$. Then

$$
\langle\varphi,(\hat{A}+1) \psi\rangle=\langle(A+1) \varphi, \psi\rangle=\langle\psi,(A+1) \varphi\rangle^{*}=\langle\psi, \varphi\rangle_{A}^{*}=\langle\varphi, \psi\rangle_{A}
$$

and by continuity we even get $\langle\varphi,(\hat{A}+1) \psi\rangle=\langle\varphi, \psi\rangle_{A}$ for every $\varphi \in \mathfrak{H}_{A}$. Hence by the definition of $\tilde{A}$ we have $\psi \in \mathfrak{D}(\tilde{A})$ and $\tilde{A} \psi=\hat{A} \psi$; that is, $\hat{A} \subseteq \tilde{A}$. But self-adjoint operators are maximal by Corollary 2.2 and thus $\hat{A}=\tilde{A}$.

Clearly $\mathfrak{Q}(A)=\mathfrak{H}_{A}$ and $q_{A}$ can be defined for semi-bounded operators as before by using $\|\psi\|_{A}=\langle\psi,(A-\gamma) \psi\rangle+\|\psi\|^{2}$.

In many physical applications, the converse of this result is also of importance: given a quadratic form $q$, when is there a corresponding operator $A$ such that $q=q_{A}$ ?

So let $q: \mathfrak{Q} \rightarrow \mathbb{C}$ be a densely defined quadratic form corresponding to a sesquilinear form $s: \mathfrak{Q} \times \mathfrak{Q} \rightarrow \mathbb{C}$; that is, $q(\psi)=s(\psi, \psi)$. As with a scalar product, $s$ can be recovered from $q$ via the polarization identity (cf. Problem 0.14). Furthermore, as in Lemma 2.1 one can show that $s$ is symmetric, $s(\varphi, \psi)=s(\psi, \varphi)^{*}$, if and only if $q$ is real-valued. In this case $q$ will be called hermitian.

A hermitian form $q$ is called nonnegative if $q(\psi) \geq 0$ and semibounded if $q(\psi) \geq \gamma\|\psi\|^{2}$ for some $\gamma \in \mathbb{R}$. As before we can associate a norm $\|\psi\|_{q}=q(\psi)+(1-\gamma)\|\psi\|^{2}$ with any semi-bounded $q$ and look at the completion $\mathfrak{H}_{q}$ of $\mathfrak{Q}$ with respect to this norm. However, since we are not assuming that $q$ is steaming from a semi-bounded operator, we do not know whether $\mathfrak{H}_{q}$ can be regarded as a subspace of $\mathfrak{H}$ ! Hence we will call $q$ closable if for every Cauchy sequence $\psi_{n} \in \mathfrak{Q}$ with respect to $\|\cdot\|_{q},\left\|\psi_{n}\right\| \rightarrow 0$ implies $\left\|\psi_{n}\right\|_{q} \rightarrow 0$. In this case we have $\mathfrak{H}_{q} \subseteq \mathfrak{H}$ and we call the extension of $q$ to $\mathfrak{H}_{q}$ the closure of $q$. In particular, we will call $q$ closed if $\mathfrak{Q}=\mathfrak{H}_{q}$.
Example. Let $\mathfrak{H}=L^{2}(0,1)$. Then

$$
q(f)=|f(c)|^{2}, \quad f \in C[0,1], \quad c \in[0,1],
$$

is a well-defined nonnegative form. However, let $f_{n}(x)=\max (0,1-n|x-c|)$. Then $f_{n}$ is a Cauchy sequence with respect to $\|\cdot\|_{q}$ such that $\left\|f_{n}\right\| \rightarrow 0$ but $\left\|f_{n}\right\|_{q} \rightarrow 1$. Hence $q$ is not closable and hence also not associated with a nonnegative operator. Formally, one can interpret $q$ as the quadratic form of the multiplication operator with the delta distribution at $x=c$. Exercise: Show $\mathfrak{H}_{q}=\mathfrak{H} \oplus \mathbb{C}$.

From our previous considerations we already know that the quadratic form $q_{A}$ of a semi-bounded operator $A$ is closable and its closure is associated with a self-adjoint operator. It turns out that the converse is also true (compare also Corollary 1.9 for the case of bounded operators):

Theorem 2.13. To every closed semi-bounded quadratic form $q$ there corresponds a unique self-adjoint operator $A$ such that $\mathfrak{Q}=\mathfrak{Q}(A)$ and $q=q_{A}$.

If $s$ is the sesquilinear form corresponding to $q$, then $A$ is given by

$$
\begin{align*}
\mathfrak{D}(A) & =\left\{\psi \in \mathfrak{H}_{q} \mid \exists \tilde{\psi} \in \mathfrak{H}: s(\varphi, \psi)=\langle\varphi, \tilde{\psi}\rangle, \forall \varphi \in \mathfrak{H}_{q}\right\},  \tag{2.60}\\
A \psi & =\tilde{\psi}-(1-\gamma) \psi .
\end{align*}
$$

Proof. Since $\mathfrak{H}_{q}$ is dense, $\tilde{\psi}$ and hence $A$ is well-defined. Moreover, replacing $q$ by $q()-.\gamma\|$.$\| and A$ by $A-\gamma$, it is no restriction to assume $\gamma=0$. As in the proof of Lemma 2.10 it follows that $A$ is a nonnegative operator, $\|A \psi\|^{2} \geq\|\psi\|^{2}$, with $\operatorname{Ran}(A+1)=\mathfrak{H}$. In particular, $(A+1)^{-1}$ exists and is bounded. Furthermore, for every $\varphi_{j} \in \mathfrak{H}$ we can find $\psi_{j} \in \mathfrak{D}(A)$ such that $\varphi_{j}=(A+1) \psi_{j}$. Finally,

$$
\begin{aligned}
\left\langle(A+1)^{-1} \varphi_{1}, \varphi_{2}\right\rangle & =\left\langle\psi_{1},(A+1) \psi_{2}\right\rangle=s\left(\psi_{1}, \psi_{2}\right)=s\left(\psi_{2}, \psi_{1}\right)^{*} \\
& =\left\langle\psi_{2},(A+1) \psi_{1}\right\rangle^{*}=\left\langle(A+1) \psi_{1}, \psi_{2}\right\rangle \\
& =\left\langle\varphi_{1},(A+1)^{-1} \varphi_{2}\right\rangle
\end{aligned}
$$

shows that $(A+1)^{-1}$ is self-adjoint and so is $A+1$ by Corollary 2.5.
Any subspace $\tilde{\mathfrak{Q}} \subseteq \mathfrak{Q}(A)$ which is dense with respect to $\|\cdot\|_{A}$ is called a form core of $A$ and uniquely determines $A$.
Example. We have already seen that the operator

$$
\begin{equation*}
A f=-\frac{d^{2}}{d x^{2}} f, \quad \mathfrak{D}(A)=\left\{f \in H^{2}[0, \pi] \mid f(0)=f(\pi)=0\right\} \tag{2.61}
\end{equation*}
$$

is associated with the closed form

$$
\begin{equation*}
q_{A}(f)=\int_{0}^{\pi}\left|f^{\prime}(x)\right|^{2} d x, \quad \mathfrak{Q}(A)=\left\{f \in H^{1}[0, \pi] \mid f(0)=f(\pi)=0\right\} . \tag{2.62}
\end{equation*}
$$

However, this quadratic form even makes sense on the larger form domain $\mathfrak{Q}=H^{1}[0, \pi]$. What is the corresponding self-adjoint operator? (See Problem 2.13.)

A hermitian form $q$ is called bounded if $|q(\psi)| \leq C\|\psi\|^{2}$ and we call

$$
\begin{equation*}
\|q\|=\sup _{\|\psi\|=1}|q(\psi)| \tag{2.63}
\end{equation*}
$$

the norm of $q$. In this case the norm $\|.\|_{q}$ is equivalent to $\|$.$\| . Hence$ $\mathfrak{H}_{q}=\mathfrak{H}$ and the corresponding operator is bounded by the Hellinger-Toeplitz theorem (Theorem 2.9). In fact, the operator norm is equal to the norm of $q$ (see also Problem 0.15):

Lemma 2.14. A semi-bounded form $q$ is bounded if and only if the associated operator $A$ is. Moreover, in this case

$$
\begin{equation*}
\|q\|=\|A\| . \tag{2.64}
\end{equation*}
$$

Proof. Using the polarization identity and the parallelogram law (Problem 0.14), we infer $2 \operatorname{Re}\langle\varphi, A \psi\rangle \leq\left(\|\psi\|^{2}+\|\varphi\|^{2}\right) \sup _{\psi}|\langle\psi, A \psi\rangle|$ and choosing $\varphi=\|A \psi\|^{-1} A \psi$ shows $\|A\| \leq \| q \mid$. The converse is easy.

As a consequence we see that for symmetric operators we have

$$
\begin{equation*}
\|A\|=\sup _{\|\psi\|=1}|\langle\psi, A \psi\rangle| \tag{2.65}
\end{equation*}
$$

generalizing (2.14) in this case.
Problem 2.10. Let $A$ be invertible. Show $A>0$ if and only if $A^{-1}>0$.
Problem 2.11. Let $A=-\frac{d^{2}}{d x^{2}}, \mathfrak{D}(A)=\left\{f \in H^{2}(0, \pi) \mid f(0)=f(\pi)=0\right\}$ and let $\psi(x)=\frac{1}{2 \sqrt{\pi}} x(\pi-x)$. Find the error in the following argument: Since $A$ is symmetric, we have $1=\langle A \psi, A \psi\rangle=\left\langle\psi, A^{2} \psi\right\rangle=0$.

Problem 2.12. Suppose $A$ is a closed operator. Show that $A^{*} A$ (with $\left.\mathfrak{D}\left(A^{*} A\right)=\left\{\psi \in \mathfrak{D}(A) \mid A \psi \in \mathfrak{D}\left(A^{*}\right)\right\}\right)$ is self-adjoint. Show $\mathfrak{Q}\left(A^{*} A\right)=$ $\mathfrak{D}(A)$. (Hint: $A^{*} A \geq 0$.)

Problem 2.13. Suppose $A_{0}$ can be written as $A_{0}=S^{*} S$. Show that the Friedrichs extension is given by $A=S^{*} \bar{S}$.

Use this to compute the Friedrichs extension of $A=-\frac{d^{2}}{d x^{2}}, \mathfrak{D}(A)=\{f \in$ $\left.C^{2}(0, \pi) \mid f(0)=f(\pi)=0\right\}$. Compute also the self-adjoint operator $\bar{S} S^{*}$ and its form domain.

Problem 2.14. Use the previous problem to compute the Friedrichs extension $A$ of $A_{0}=-\frac{d^{2}}{d x^{2}}, \mathfrak{D}\left(A_{0}\right)=C_{c}^{\infty}(\mathbb{R})$. Show that $\mathfrak{Q}(A)=H^{1}(\mathbb{R})$ and $\mathfrak{D}(A)=H^{2}(\mathbb{R})$. (Hint: Section 2.7.)

Problem 2.15. Let $A$ be self-adjoint. Suppose $\mathfrak{D} \subseteq \mathfrak{D}(A)$ is a core. Then $\mathfrak{D}$ is also a form core.

Problem 2.16. Show that (2.65) is wrong if $A$ is not symmetric.

### 2.4. Resolvents and spectra

Let $A$ be a (densely defined) closed operator. The resolvent set of $A$ is defined by

$$
\begin{equation*}
\rho(A)=\left\{z \in \mathbb{C} \mid(A-z)^{-1} \in \mathfrak{L}(\mathfrak{H})\right\} . \tag{2.66}
\end{equation*}
$$

More precisely, $z \in \rho(A)$ if and only if $(A-z): \mathfrak{D}(A) \rightarrow \mathfrak{H}$ is bijective and its inverse is bounded. By the closed graph theorem (Theorem 2.8), it suffices to check that $A-z$ is bijective. The complement of the resolvent set is called the spectrum

$$
\begin{equation*}
\sigma(A)=\mathbb{C} \backslash \rho(A) \tag{2.67}
\end{equation*}
$$

of $A$. In particular, $z \in \sigma(A)$ if $A-z$ has a nontrivial kernel. A vector $\psi \in \operatorname{Ker}(A-z)$ is called an eigenvector and $z$ is called an eigenvalue in this case.

The function
is called the resolvent of $A$. Note the convenient formula

$$
\begin{equation*}
R_{A}(z)^{*}=\left((A-z)^{-1}\right)^{*}=\left((A-z)^{*}\right)^{-1}=\left(A^{*}-z^{*}\right)^{-1}=R_{A^{*}}\left(z^{*}\right) . \tag{2.69}
\end{equation*}
$$

In particular,

$$
\begin{equation*}
\rho\left(A^{*}\right)=\rho(A)^{*} \tag{2.70}
\end{equation*}
$$

Example. (Multiplication operator) Consider again the multiplication operator

$$
\begin{equation*}
(A f)(x)=A(x) f(x), \quad \mathfrak{D}(A)=\left\{f \in L^{2}\left(\mathbb{R}^{n}, d \mu\right) \mid A f \in L^{2}\left(\mathbb{R}^{n}, d \mu\right)\right\}, \tag{2.71}
\end{equation*}
$$

given by multiplication with the measurable function $A: \mathbb{R}^{n} \rightarrow \mathbb{C}$. Clearly $(A-z)^{-1}$ is given by the multiplication operator

$$
\begin{align*}
(A-z)^{-1} f(x) & =\frac{1}{A(x)-z} f(x) \\
\mathfrak{D}\left((A-z)^{-1}\right) & =\left\{f \in L^{2}\left(\mathbb{R}^{n}, d \mu\right) \left\lvert\, \frac{1}{A-z} f \in L^{2}\left(\mathbb{R}^{n}, d \mu\right)\right.\right\} \tag{2.72}
\end{align*}
$$

whenever this operator is bounded. But $\left\|(A-z)^{-1}\right\|=\left\|\frac{1}{A-z}\right\|_{\infty} \leq \frac{1}{\varepsilon}$ is equivalent to $\mu(\{x||A(x)-z|<\varepsilon\})=0$ and hence

$$
\begin{equation*}
\rho(A)=\{z \in \mathbb{C} \mid \exists \varepsilon>0: \mu(\{x| | A(x)-z \mid<\varepsilon\})=0\} . \tag{2.73}
\end{equation*}
$$

The spectrum

$$
\begin{equation*}
\sigma(A)=\{z \in \mathbb{C} \mid \forall \varepsilon>0: \mu(\{x| | A(x)-z \mid<\varepsilon\})>0\} \tag{2.74}
\end{equation*}
$$

is also known as the essential range of $A(x)$. Moreover, $z$ is an eigenvalue of $A$ if $\mu\left(A^{-1}(\{z\})\right)>0$ and $\chi_{A^{-1}(\{z\})}$ is a corresponding eigenfunction in this case.

Example. (Differential operator) Consider again the differential operator

$$
\begin{equation*}
A f=-\mathrm{i} \frac{d}{d x} f, \quad \mathfrak{D}(A)=\left\{f \in A C[0,2 \pi] \mid f^{\prime} \in L^{2}, f(0)=f(2 \pi)\right\} \tag{2.75}
\end{equation*}
$$

in $L^{2}(0,2 \pi)$. We already know that the eigenvalues of $A$ are the integers and that the corresponding normalized eigenfunctions

$$
\begin{equation*}
u_{n}(x)=\frac{1}{\sqrt{2 \pi}} \mathrm{e}^{\mathrm{i} n x} \tag{2.76}
\end{equation*}
$$

form an orthonormal basis.

To compute the resolvent, we must find the solution of the corresponding inhomogeneous equation $-\mathrm{i} f^{\prime}(x)-z f(x)=g(x)$. By the variation of constants formula the solution is given by (this can also be easily verified directly)

$$
\begin{equation*}
f(x)=f(0) \mathrm{e}^{\mathrm{i} z x}+\mathrm{i} \int_{0}^{x} \mathrm{e}^{\mathrm{i} z(x-t)} g(t) d t . \tag{2.77}
\end{equation*}
$$

Since $f$ must lie in the domain of $A$, we must have $f(0)=f(2 \pi)$ which gives

$$
\begin{equation*}
f(0)=\frac{\mathrm{i}}{\mathrm{e}^{-2 \pi \mathrm{i} z}-1} \int_{0}^{2 \pi} \mathrm{e}^{-\mathrm{i} z t} g(t) d t, \quad z \in \mathbb{C} \backslash \mathbb{Z} \tag{2.78}
\end{equation*}
$$

(Since $z \in \mathbb{Z}$ are the eigenvalues, the inverse cannot exist in this case.) Hence

$$
\begin{equation*}
(A-z)^{-1} g(x)=\int_{0}^{2 \pi} G(z, x, t) g(t) d t \tag{2.79}
\end{equation*}
$$

where

$$
G(z, x, t)=\mathrm{e}^{\mathrm{i} z(x-t)}\left\{\begin{array}{ll}
\frac{-\mathrm{i}}{1-\mathrm{e}^{-2 \pi \mathrm{i} \mathrm{z}}}, & t>x,  \tag{2.80}\\
\frac{\mathrm{i}}{1-\mathrm{e}^{2 \pi \mathrm{i} z}}, & t<x,
\end{array} \quad z \in \mathbb{C} \backslash \mathbb{Z} .\right.
$$

In particular $\sigma(A)=\mathbb{Z}$.
If $z, z^{\prime} \in \rho(A)$, we have the first resolvent formula

$$
\begin{equation*}
R_{A}(z)-R_{A}\left(z^{\prime}\right)=\left(z-z^{\prime}\right) R_{A}(z) R_{A}\left(z^{\prime}\right)=\left(z-z^{\prime}\right) R_{A}\left(z^{\prime}\right) R_{A}(z) . \tag{2.81}
\end{equation*}
$$

In fact,

$$
\begin{align*}
& (A-z)^{-1}-\left(z-z^{\prime}\right)(A-z)^{-1}\left(A-z^{\prime}\right)^{-1} \\
& \quad=(A-z)^{-1}\left(1-\left(z-A+A-z^{\prime}\right)\left(A-z^{\prime}\right)^{-1}\right)=\left(A-z^{\prime}\right)^{-1} \tag{2.82}
\end{align*}
$$

which proves the first equality. The second follows after interchanging $z$ and $z^{\prime}$. Now fix $z^{\prime}=z_{0}$ and use (2.81) recursively to obtain

$$
\begin{equation*}
R_{A}(z)=\sum_{j=0}^{n}\left(z-z_{0}\right)^{j} R_{A}\left(z_{0}\right)^{j+1}+\left(z-z_{0}\right)^{n+1} R_{A}\left(z_{0}\right)^{n+1} R_{A}(z) . \tag{2.83}
\end{equation*}
$$

The sequence of bounded operators

$$
\begin{equation*}
R_{n}=\sum_{j=0}^{n}\left(z-z_{0}\right)^{j} R_{A}\left(z_{0}\right)^{j+1} \tag{2.84}
\end{equation*}
$$

converges to a bounded operator if $\left|z-z_{0}\right|<\left\|R_{A}\left(z_{0}\right)\right\|^{-1}$ and clearly we expect $z \in \rho(A)$ and $R_{n} \rightarrow R_{A}(z)$ in this case. Let $R_{\infty}=\lim _{n \rightarrow \infty} R_{n}$ and set $\varphi_{n}=R_{n} \psi, \varphi=R_{\infty} \psi$ for some $\psi \in \mathfrak{H}$. Then a quick calculation shows

$$
\begin{equation*}
A R_{n} \psi=\left(A-z_{0}\right) R_{n} \psi+z_{0} \varphi_{n}=\psi+\left(z-z_{0}\right) \varphi_{n-1}+z_{0} \varphi_{n} . \tag{2.85}
\end{equation*}
$$

Hence $\left(\varphi_{n}, A \varphi_{n}\right) \rightarrow(\varphi, \psi+z \varphi)$ shows $\varphi \in \mathfrak{D}(A)$ (since $A$ is closed) and $(A-z) R_{\infty} \psi=\psi$. Similarly, for $\psi \in \mathfrak{D}(A)$,

$$
\begin{equation*}
R_{n} A \psi=\psi+\left(z-z_{0}\right) \varphi_{n-1}+z_{0} \varphi_{n} \tag{2.86}
\end{equation*}
$$

and hence $R_{\infty}(A-z) \psi=\psi$ after taking the limit. Thus $R_{\infty}=R_{A}(z)$ as anticipated.

If $A$ is bounded, a similar argument verifies the Neumann series for the resolvent

$$
\begin{align*}
R_{A}(z) & =-\sum_{j=0}^{n-1} \frac{A^{j}}{z^{j+1}}+\frac{1}{z^{n}} A^{n} R_{A}(z) \\
& =-\sum_{j=0}^{\infty} \frac{A^{j}}{z^{j+1}}, \quad|z|>\|A\| . \tag{2.87}
\end{align*}
$$

In summary we have proved the following:
Theorem 2.15. The resolvent set $\rho(A)$ is open and $R_{A}: \rho(A) \rightarrow \mathfrak{L}(\mathfrak{H})$ is holomorphic; that is, it has an absolutely convergent power series expansion around every point $z_{0} \in \rho(A)$. In addition,

$$
\begin{equation*}
\left\|R_{A}(z)\right\| \geq \operatorname{dist}(z, \sigma(A))^{-1} \tag{2.88}
\end{equation*}
$$

and if $A$ is bounded, we have $\{z \in \mathbb{C}||z|>\|A\|\} \subseteq \rho(A)$.
As a consequence we obtain the useful
Lemma 2.16. We have $z \in \sigma(A)$ if there is a sequence $\psi_{n} \in \mathfrak{D}(A)$ such that $\left\|\psi_{n}\right\|=1$ and $\left\|(A-z) \psi_{n}\right\| \rightarrow 0$. If $z$ is a boundary point of $\rho(A)$, then the converse is also true. Such a sequence is called a Weyl sequence.

Proof. Let $\psi_{n}$ be a Weyl sequence. Then $z \in \rho(A)$ is impossible by $1=$ $\left\|\psi_{n}\right\|=\left\|R_{A}(z)(A-z) \psi_{n}\right\| \leq\left\|R_{A}(z)\right\|\left\|(A-z) \psi_{n}\right\| \rightarrow 0$. Conversely, by (2.88) there is a sequence $z_{n} \rightarrow z$ and corresponding vectors $\varphi_{n} \in \mathfrak{H}$ such that $\left\|R_{A}(z) \varphi_{n}\right\|\left\|\varphi_{n}\right\|^{-1} \rightarrow \infty$. Let $\psi_{n}=R_{A}\left(z_{n}\right) \varphi_{n}$ and rescale $\varphi_{n}$ such that $\left\|\psi_{n}\right\|=1$. Then $\left\|\varphi_{n}\right\| \rightarrow 0$ and hence

$$
\left\|(A-z) \psi_{n}\right\|=\left\|\varphi_{n}+\left(z_{n}-z\right) \psi_{n}\right\| \leq\left\|\varphi_{n}\right\|+\left|z-z_{n}\right| \rightarrow 0
$$

shows that $\psi_{n}$ is a Weyl sequence.
Let us also note the following spectral mapping result.
Lemma 2.17. Suppose $A$ is injective. Then

$$
\begin{equation*}
\sigma\left(A^{-1}\right) \backslash\{0\}=(\sigma(A) \backslash\{0\})^{-1} \tag{2.89}
\end{equation*}
$$

In addition, we have $A \psi=z \psi$ if and only if $A^{-1} \psi=z^{-1} \psi$.
Proof. Suppose $z \in \rho(A) \backslash\{0\}$. Then we claim

$$
R_{A^{-1}}\left(z^{-1}\right)=-z A R_{A}(z)=-z-z^{2} R_{A}(z) .
$$

In fact, the right-hand side is a bounded operator from $\mathfrak{H} \rightarrow \operatorname{Ran}(A)=$ $\mathfrak{D}\left(A^{-1}\right)$ and

$$
\left(A^{-1}-z^{-1}\right)\left(-z A R_{A}(z)\right) \varphi=(-z+A) R_{A}(z) \varphi=\varphi, \quad \varphi \in \mathfrak{H} .
$$

Conversely, if $\psi \in \mathfrak{D}\left(A^{-1}\right)=\operatorname{Ran}(A)$, we have $\psi=A \varphi$ and hence

$$
\left(-z A R_{A}(z)\right)\left(A^{-1}-z^{-1}\right) \psi=A R_{A}(z)((A-z) \varphi)=A \varphi=\psi
$$

Thus $z^{-1} \in \rho\left(A^{-1}\right)$. The rest follows after interchanging the roles of $A$ and $A^{-1}$.

Next, let us characterize the spectra of self-adjoint operators.
Theorem 2.18. Let $A$ be symmetric. Then $A$ is self-adjoint if and only if $\sigma(A) \subseteq \mathbb{R}$ and $(A-E) \geq 0, E \in \mathbb{R}$, if and only if $\sigma(A) \subseteq[E, \infty)$. Moreover, $\left\|R_{A}(z)\right\| \leq|\operatorname{Im}(z)|^{-1}$ and, if $(A-E) \geq 0,\left\|R_{A}(\lambda)\right\| \leq|\lambda-E|^{-1}, \lambda<E$.

Proof. If $\sigma(A) \subseteq \mathbb{R}$, then $\operatorname{Ran}(A+z)=\mathfrak{H}, z \in \mathbb{C} \backslash \mathbb{R}$, and hence $A$ is self-adjoint by Lemma 2.7. Conversely, if $A$ is self-adjoint (resp. $A \geq E$ ), then $R_{A}(z)$ exists for $z \in \mathbb{C} \backslash \mathbb{R}$ (resp. $z \in \mathbb{C} \backslash[E, \infty)$ ) and satisfies the given estimates as has been shown in the proof of Lemma 2.7.

In particular, we obtain (show this!)
Theorem 2.19. Let $A$ be self-adjoint. Then

$$
\begin{equation*}
\inf \sigma(A)=\inf _{\psi \in \mathfrak{D}(A),\|\psi\|=1}\langle\psi, A \psi\rangle \tag{2.90}
\end{equation*}
$$

and

$$
\begin{equation*}
\sup \sigma(A)=\sup _{\psi \in \mathfrak{D}(A),\|\psi\|=1}\langle\psi, A \psi\rangle . \tag{2.91}
\end{equation*}
$$

For the eigenvalues and corresponding eigenfunctions we have
Lemma 2.20. Let $A$ be symmetric. Then all eigenvalues are real and eigenvectors corresponding to different eigenvalues are orthogonal.

Proof. If $A \psi_{j}=\lambda_{j} \psi_{j}, j=1,2$, we have

$$
\lambda_{1}\left\|\psi_{1}\right\|^{2}=\left\langle\psi_{1}, \lambda_{1} \psi_{1}\right\rangle=\left\langle\psi_{1}, A \psi_{1}\right\rangle=\left\langle\psi_{1}, A \psi_{1}\right\rangle=\left\langle\lambda_{1} \psi_{1}, \psi_{1}\right\rangle=\lambda_{1}^{*}\left\|\psi_{1}\right\|^{2}
$$

and

$$
\left(\lambda_{1}-\lambda_{2}\right)\left\langle\psi_{1}, \psi_{2}\right\rangle=\left\langle A \psi_{1}, \psi_{2}\right\rangle-\left\langle A \psi_{1}, \psi_{2}\right\rangle=0,
$$

finishing the proof.
The result does not imply that two linearly independent eigenfunctions to the same eigenvalue are orthogonal. However, it is no restriction to assume that they are since we can use Gram-Schmidt to find an orthonormal basis for $\operatorname{Ker}(A-\lambda)$. If $\mathfrak{H}$ is finite dimensional, we can always find an orthonormal basis of eigenvectors. In the infinite dimensional case this is
no longer true in general. However, if there is an orthonormal basis of eigenvectors, then $A$ is essentially self-adjoint.

Theorem 2.21. Suppose $A$ is a symmetric operator which has an orthonormal basis of eigenfunctions $\left\{\varphi_{j}\right\}$. Then $A$ is essentially self-adjoint. In particular, it is essentially self-adjoint on $\operatorname{span}\left\{\varphi_{j}\right\}$.

Proof. Consider the set of all finite linear combinations $\psi=\sum_{j=0}^{n} c_{j} \varphi_{j}$ which is dense in $\mathfrak{H}$. Then $\phi=\sum_{j=0}^{n} \frac{c_{j}}{\lambda_{j} \pm \mathrm{i}} \varphi_{j} \in \mathfrak{D}(A)$ and $(A \pm \mathrm{i}) \phi=\psi$ shows that $\operatorname{Ran}(A \pm \mathrm{i})$ is dense.

Similarly, we can characterize the spectra of unitary operators. Recall that a bijection $U$ is called unitary if $\langle U \psi, U \psi\rangle=\left\langle\psi, U^{*} U \psi\right\rangle=\langle\psi, \psi\rangle$. Thus $U$ is unitary if and only if

$$
\begin{equation*}
U^{*}=U^{-1} \tag{2.92}
\end{equation*}
$$

Theorem 2.22. Let $U$ be unitary. Then $\sigma(U) \subseteq\{z \in \mathbb{C}||z|=1\}$. All eigenvalues have modulus one and eigenvectors corresponding to different eigenvalues are orthogonal.

Proof. Since $\|U\| \leq 1$, we have $\sigma(U) \subseteq\left\{z \in \mathbb{C}||z| \leq 1\}\right.$. Moreover, $U^{-1}$ is also unitary and hence $\sigma(U) \subseteq\{z \in \mathbb{C}||z| \geq 1\}$ by Lemma 2.17. If $U \psi_{j}=z_{j} \psi_{j}, j=1,2$, we have

$$
\left(z_{1}-z_{2}\right)\left\langle\psi_{1}, \psi_{2}\right\rangle=\left\langle U^{*} \psi_{1}, \psi_{2}\right\rangle-\left\langle\psi_{1}, U \psi_{2}\right\rangle=0
$$

since $U \psi=z \psi$ implies $U^{*} \psi=U^{-1} \psi=z^{-1} \psi=z^{*} \psi$.
Problem 2.17. Suppose $A$ is closed and $B$ bounded:

- Show that $\mathbb{I}+B$ has a bounded inverse if $\|B\|<1$.
- Suppose $A$ has a bounded inverse. Then so does $A+B$ if $\|B\| \leq$ $\left\|A^{-1}\right\|^{-1}$.

Problem 2.18. What is the spectrum of an orthogonal projection?
Problem 2.19. Compute the resolvent of

$$
A f=f^{\prime}, \quad \mathfrak{D}(A)=\left\{f \in H^{1}[0,1] \mid f(0)=0\right\}
$$

and show that unbounded operators can have empty spectrum.
Problem 2.20. Compute the eigenvalues and eigenvectors of $A=-\frac{d^{2}}{d x^{2}}$, $\mathfrak{D}(A)=\left\{f \in H^{2}(0, \pi) \mid f(0)=f(\pi)=0\right\}$. Compute the resolvent of $A$.

Problem 2.21. Find a Weyl sequence for the self-adjoint operator $A=$ $-\frac{d^{2}}{d x^{2}}, \mathfrak{D}(A)=H^{2}(\mathbb{R})$ for $z \in(0, \infty)$. What is $\sigma(A)$ ? (Hint: Cut off the solutions of $-u^{\prime \prime}(x)=z u(x)$ outside a finite ball.)

Problem 2.22. Suppose $A=\overline{A_{0}}$. If $\psi_{n} \in \mathfrak{D}(A)$ is a Weyl sequence for $z \in \sigma(A)$, then there is also one with $\tilde{\psi}_{n} \in \mathfrak{D}\left(A_{0}\right)$.

Problem 2.23. Suppose $A$ is bounded. Show that the spectra of $A A^{*}$ and $A^{*} A$ coincide away from 0 by showing

$$
\begin{equation*}
R_{A A^{*}}(z)=\frac{1}{z}\left(A R_{A^{*} A}(z) A^{*}-1\right), \quad R_{A^{*} A}(z)=\frac{1}{z}\left(A^{*} R_{A A^{*}}(z) A-1\right) . \tag{2.93}
\end{equation*}
$$

### 2.5. Orthogonal sums of operators

Let $\mathfrak{H}_{j}, j=1,2$, be two given Hilbert spaces and let $A_{j}: \mathfrak{D}\left(A_{j}\right) \rightarrow \mathfrak{H}_{j}$ be two given operators. Setting $\mathfrak{H}=\mathfrak{H}_{1} \oplus \mathfrak{H}_{2}$, we can define an operator

$$
\begin{equation*}
A=A_{1} \oplus A_{2}, \quad \mathfrak{D}(A)=\mathfrak{D}\left(A_{1}\right) \oplus \mathfrak{D}\left(A_{2}\right) \tag{2.94}
\end{equation*}
$$

by setting $A\left(\psi_{1}+\psi_{2}\right)=A_{1} \psi_{1}+A_{2} \psi_{2}$ for $\psi_{j} \in \mathfrak{D}\left(A_{j}\right)$. Clearly $A$ is closed, (essentially) self-adjoint, etc., if and only if both $A_{1}$ and $A_{2}$ are. The same considerations apply to countable orthogonal sums. Let $\mathfrak{H}=\bigoplus_{j} \mathfrak{H}_{j}$ and set

$$
\begin{equation*}
A=\bigoplus_{j} A_{j}, \quad \mathfrak{D}(A)=\left\{\psi \in \bigoplus_{j} \mathfrak{D}\left(A_{j}\right) \mid A \psi \in \mathfrak{H}\right\} . \tag{2.95}
\end{equation*}
$$

Then we have
Theorem 2.23. Suppose $A_{j}$ are self-adjoint operators on $\mathfrak{H}_{j}$. Then $A=$ $\bigoplus_{j} A_{j}$ is self-adjoint and

$$
\begin{equation*}
R_{A}(z)=\bigoplus_{j} R_{A_{j}}(z), \quad z \in \rho(A)=\mathbb{C} \backslash \sigma(A) \tag{2.96}
\end{equation*}
$$

where

$$
\begin{equation*}
\sigma(A)=\overline{\bigcup_{j} \sigma\left(A_{j}\right)} \tag{2.97}
\end{equation*}
$$

(the closure can be omitted if there are only finitely many terms).
Proof. Fix $z \notin \overline{\bigcup_{j} \sigma\left(A_{j}\right)}$ and let $\varepsilon=\operatorname{Im}(z)$. Then, by Theorem 2.18, $\left\|R_{A_{j}}(z)\right\| \leq \varepsilon^{-1}$ and so $R(z)=\bigoplus_{j} R_{A_{j}}(z)$ is a bounded operator with $\|R(z)\| \leq \varepsilon^{-1}$ (cf. Problem 2.26). It is straightforward to check that $R(z)$ is in fact the resolvent of $A$ and thus $\sigma(A) \subseteq \mathbb{R}$. In particular, $A$ is selfadjoint by Theorem 2.18. To see that $\sigma(A) \subseteq \overline{\bigcup_{j} \sigma\left(A_{j}\right)}$, note that the above argument can be repeated with $\varepsilon=\operatorname{dist}\left(z, \bigcup_{j} \sigma\left(A_{j}\right)\right)>0$, which will follow from the spectral theorem (Problem 3.5) to be proven in the next chapter. Conversely, if $z \in \sigma\left(A_{j}\right)$, there is a corresponding Weyl sequence $\psi_{n} \in \mathfrak{D}\left(A_{j}\right) \subseteq \mathfrak{D}(A)$ and hence $z \in \sigma(A)$.

Conversely, given an operator $A$, it might be useful to write $A$ as an orthogonal sum and investigate each part separately.

Let $\mathfrak{H}_{1} \subseteq \mathfrak{H}$ be a closed subspace and let $P_{1}$ be the corresponding projector. We say that $\mathfrak{H}_{1}$ reduces the operator $A$ if $P_{1} A \subseteq A P_{1}$. Note that this is equivalent to $P_{1} \mathfrak{D}(A) \subseteq \mathfrak{D}(A)$ and $P_{1} A \psi=A P_{1} \psi$ for $\psi \in \mathfrak{D}(A)$. Moreover, if we set $\mathfrak{H}_{2}=\mathfrak{H}_{1}^{\perp}$, we have $\mathfrak{H}=\mathfrak{H}_{1} \oplus \mathfrak{H}_{2}$ and $P_{2}=1-P_{1}$ reduces $A$ as well.

Lemma 2.24. Suppose $\mathfrak{H}=\bigoplus_{j} \mathfrak{H}_{j}$ where each $\mathfrak{H}_{j}$ reduces $A$. Then $A=$ $\bigoplus_{j} A_{j}$, where

$$
\begin{equation*}
A_{j} \psi=A \psi, \quad \mathfrak{D}\left(A_{j}\right)=P_{j} \mathfrak{D}(A) \subseteq \mathfrak{D}(A) \tag{2.98}
\end{equation*}
$$

If $A$ is closable, then $\mathfrak{H}_{j}$ also reduces $\bar{A}$ and

$$
\begin{equation*}
\bar{A}=\bigoplus_{j} \overline{A_{j}} . \tag{2.99}
\end{equation*}
$$

Proof. As already noted, $P_{j} \mathfrak{D}(A) \subseteq \mathfrak{D}(A)$ and thus every $\psi \in \mathfrak{D}(A)$ can be written as $\psi=\sum_{j} P_{j} \psi$; that is, $\mathfrak{D}(A)=\bigoplus_{j} \mathfrak{D}\left(A_{j}\right)$. Moreover, if $\psi \in \mathfrak{D}\left(A_{j}\right)$, we have $A \psi=A P_{j} \psi=P_{j} A \psi \in \mathfrak{H}_{j}$ and thus $A_{j}: \mathfrak{D}\left(A_{j}\right) \rightarrow \mathfrak{H}_{j}$ which proves the first claim.

Now let us turn to the second claim. Suppose $\psi \in \mathfrak{D}(\bar{A})$. Then there is a sequence $\psi_{n} \in \mathfrak{D}(A)$ such that $\psi_{n} \rightarrow \psi$ and $A \psi_{n} \rightarrow \varphi=\bar{A} \psi$. Thus $P_{j} \psi_{n} \rightarrow P_{j} \psi$ and $A P_{j} \psi_{n}=P_{j} A \psi_{n} \rightarrow P_{j} \varphi$ which shows $P_{j} \psi \in \mathfrak{D}(\bar{A})$ and $P_{j} \bar{A} \psi=\bar{A} P_{j} \psi ;$ that is, $\mathfrak{H}_{j}$ reduces $\bar{A}$. Moreover, this argument also shows $P_{j} \mathfrak{D}(\bar{A}) \subseteq \mathfrak{D}\left(\overline{A_{j}}\right)$ and the converse follows analogously.

If $A$ is self-adjoint, then $\mathfrak{H}_{1}$ reduces $A$ if $P_{1} \mathfrak{D}(A) \subseteq \mathfrak{D}(A)$ and $A P_{1} \psi \in \mathfrak{H}_{1}$ for every $\psi \in \mathfrak{D}(A)$. In fact, if $\psi \in \mathfrak{D}(A)$, we can write $\psi=\psi_{1} \oplus \psi_{2}$, with $P_{2}=1-P_{1}$ and $\psi_{j}=P_{j} \psi \in \mathfrak{D}(A)$. Since $A P_{1} \psi=A \psi_{1}$ and $P_{1} A \psi=$ $P_{1} A \psi_{1}+P_{1} A \psi_{2}=A \psi_{1}+P_{1} A \psi_{2}$, we need to show $P_{1} A \psi_{2}=0$. But this follows since

$$
\begin{equation*}
\left\langle\varphi, P_{1} A \psi_{2}\right\rangle=\left\langle A P_{1} \varphi, \psi_{2}\right\rangle=0 \tag{2.100}
\end{equation*}
$$

for every $\varphi \in \mathfrak{D}(A)$.
Problem 2.24. Show $\left(\bigoplus_{j} A_{j}\right)^{*}=\bigoplus_{j} A_{j}^{*}$.
Problem 2.25. Show that $A$ defined in (2.95) is closed if and only if all $A_{j}$ are.

Problem 2.26. Show that for $A$ defined in (2.95), we have $\|A\|=\sup _{j}\left\|A_{j}\right\|$.

### 2.6. Self-adjoint extensions

It is safe to skip this entire section on first reading.
In many physical applications a symmetric operator is given. If this operator turns out to be essentially self-adjoint, there is a unique self-adjoint extension and everything is fine. However, if it is not, it is important to find out if there are self-adjoint extensions at all (for physical problems there better be) and to classify them.

In Section 2.2 we saw that $A$ is essentially self-adjoint if $\operatorname{Ker}\left(A^{*}-z\right)=$ $\operatorname{Ker}\left(A^{*}-z^{*}\right)=\{0\}$ for one $z \in \mathbb{C} \backslash \mathbb{R}$. Hence self-adjointness is related to the dimension of these spaces and one calls the numbers

$$
\begin{equation*}
d_{ \pm}(A)=\operatorname{dim} K_{ \pm}, \quad K_{ \pm}=\operatorname{Ran}(A \pm \mathrm{i})^{\perp}=\operatorname{Ker}\left(A^{*} \mp \mathrm{i}\right), \tag{2.101}
\end{equation*}
$$

defect indices of $A$ (we have chosen $z=\mathrm{i}$ for simplicity; any other $z \in \mathbb{C} \backslash \mathbb{R}$ would be as good). If $d_{-}(A)=d_{+}(A)=0$, there is one self-adjoint extension of $A$, namely $\bar{A}$. But what happens in the general case? Is there more than one extension, or maybe none at all? These questions can be answered by virtue of the Cayley transform

$$
\begin{equation*}
V=(A-\mathrm{i})(A+\mathrm{i})^{-1}: \operatorname{Ran}(A+\mathrm{i}) \rightarrow \operatorname{Ran}(A-\mathrm{i}) . \tag{2.102}
\end{equation*}
$$

Theorem 2.25. The Cayley transform is a bijection from the set of all symmetric operators $A$ to the set of all isometric operators $V$ (i.e., $\|V \varphi\|=$ $\|\varphi\|$ for all $\varphi \in \mathfrak{D}(V))$ for which $\operatorname{Ran}(1-V)$ is dense.

Proof. Since $A$ is symmetric, we have $\|(A \pm \mathrm{i}) \psi\|^{2}=\|A \psi\|^{2}+\|\psi\|^{2}$ for all $\psi \in \mathfrak{D}(A)$ by a straightforward computation. Thus for every $\varphi=(A+\mathrm{i}) \psi \in$ $\mathfrak{D}(V)=\operatorname{Ran}(A+\mathrm{i})$ we have

$$
\|V \varphi\|=\|(A-\mathrm{i}) \psi\|=\|(A+\mathrm{i}) \psi\|=\|\varphi\| .
$$

Next observe

$$
1 \pm V=((A-\mathrm{i}) \pm(A+\mathrm{i}))(A+\mathrm{i})^{-1}=\left\{\begin{array}{c}
2 A(A+\mathrm{i})^{-1} \\
2 \mathrm{i}(A+\mathrm{i})^{-1}
\end{array}\right.
$$

which shows that $\operatorname{Ran}(1-V)=\mathfrak{D}(A)$ is dense and

$$
A=\mathrm{i}(1+V)(1-V)^{-1} .
$$

Conversely, let $V$ be given and use the last equation to define $A$.
Since $V$ is isometric, we have $\langle(1 \pm V) \varphi,(1 \mp V) \varphi\rangle= \pm 2 \mathrm{i} \operatorname{Im}\langle V \varphi, \varphi\rangle$ for all $\varphi \in \mathfrak{D}(V)$ by a straightforward computation. Thus for every $\psi=$ $(1-V) \varphi \in \mathfrak{D}(A)=\operatorname{Ran}(1-V)$ we have

$$
\langle A \psi, \psi\rangle=-\mathrm{i}\langle(1+V) \varphi,(1-V) \varphi\rangle=\mathrm{i}\langle(1-V) \varphi,(1+V) \varphi\rangle=\langle\psi, A \psi\rangle ;
$$

that is, $A$ is symmetric. Finally observe

$$
A \pm \mathrm{i}=((1+V) \pm(1-V))(1-V)^{-1}=\left\{\begin{array}{c}
2 \mathrm{i}(1-V)^{-1} \\
2 \mathrm{i} V(1-V)^{-1}
\end{array}\right.
$$

which shows that $A$ is the Cayley transform of $V$ and finishes the proof.
Thus $A$ is self-adjoint if and only if its Cayley transform $V$ is unitary. Moreover, finding a self-adjoint extension of $A$ is equivalent to finding a unitary extensions of $V$ and this in turn is equivalent to (taking the closure and) finding a unitary operator from $\mathfrak{D}(V)^{\perp}$ to $\operatorname{Ran}(V)^{\perp}$. This is possible if and only if both spaces have the same dimension, that is, if and only if $d_{+}(A)=d_{-}(A)$.
Theorem 2.26. A symmetric operator has self-adjoint extensions if and only if its defect indices are equal.

In this case let $A_{1}$ be a self-adjoint extension and $V_{1}$ its Cayley transform. Then

$$
\begin{equation*}
\mathfrak{D}\left(A_{1}\right)=\mathfrak{D}(A)+\left(1-V_{1}\right) K_{+}=\left\{\psi+\varphi_{+}-V_{1} \varphi_{+} \mid \psi \in \mathfrak{D}(A), \varphi_{+} \in K_{+}\right\} \tag{2.103}
\end{equation*}
$$

and

$$
\begin{equation*}
A_{1}\left(\psi+\varphi_{+}-V_{1} \varphi_{+}\right)=A \psi+\mathrm{i} \varphi_{+}+\mathrm{i} V_{1} \varphi_{+} \tag{2.104}
\end{equation*}
$$

Moreover,

$$
\begin{equation*}
\left(A_{1} \pm \mathrm{i}\right)^{-1}=(A \pm \mathrm{i})^{-1} \oplus \frac{\mp \mathrm{i}}{2} \sum_{j}\left\langle\varphi_{j}^{ \pm}, .\right\rangle\left(\varphi_{j}^{ \pm}-\varphi_{j}^{\mp}\right), \tag{2.105}
\end{equation*}
$$

where $\left\{\varphi_{j}^{+}\right\}$is an orthonormal basis for $K_{+}$and $\varphi_{j}^{-}=V_{1} \varphi_{j}^{+}$.
Proof. From the proof of the previous theorem we know that $\mathfrak{D}\left(A_{1}\right)=$ $\operatorname{Ran}\left(1-V_{1}\right)=\operatorname{Ran}(1+V)+\left(1-V_{1}\right) K_{+}=\mathfrak{D}(A)+\left(1-V_{1}\right) K_{+}$. Moreover, $A_{1}\left(\psi+\varphi_{+}-V_{1} \varphi_{+}\right)=A \psi+\mathrm{i}\left(1+V_{1}\right)\left(1-V_{1}\right)^{-1}\left(1-V_{1}\right) \varphi_{+}=A \psi+\mathrm{i}\left(1+V_{1}\right) \varphi_{+}$.

Similarly, $\operatorname{Ran}\left(A_{1} \pm \mathrm{i}\right)=\operatorname{Ran}(A \pm \mathrm{i}) \oplus K_{ \pm}$and $\left(A_{1}+\mathrm{i}\right)^{-1}=-\frac{\mathrm{i}}{2}\left(1-V_{1}\right)$, respectively, $\left(A_{1}+\mathrm{i}\right)^{-1}=-\frac{\mathrm{i}}{2}\left(1-V_{1}^{-1}\right)$.

Note that instead of $z=\mathrm{i}$ we could use $V(z)=\left(A+z^{*}\right)(A+z)^{-1}$ for any $z \in \mathbb{C} \backslash \mathbb{R}$. We remark that in this case one can show that the defect indices are independent of $z \in \mathbb{C}_{+}=\{z \in \mathbb{C} \mid \operatorname{Im}(z)>0\}$.
Example. Recall the operator $A=-\mathrm{i} \frac{d}{d x}, \mathfrak{D}(A)=\left\{f \in H^{1}(0,2 \pi) \mid f(0)=\right.$ $f(2 \pi)=0\}$ with adjoint $A^{*}=-\mathrm{i} \frac{d}{d x}, \mathfrak{D}\left(A^{*}\right)=H^{1}(0,2 \pi)$.

Clearly

$$
\begin{equation*}
K_{ \pm}=\operatorname{span}\left\{\mathrm{e}^{\mp x}\right\} \tag{2.106}
\end{equation*}
$$

is one-dimensional and hence all unitary maps are of the form

$$
\begin{equation*}
V_{\theta} \mathrm{e}^{2 \pi-x}=\mathrm{e}^{\mathrm{i} \theta} \mathrm{e}^{x}, \quad \theta \in[0,2 \pi) \tag{2.107}
\end{equation*}
$$

The functions in the domain of the corresponding operator $A_{\theta}$ are given by

$$
\begin{equation*}
f_{\theta}(x)=f(x)+\alpha\left(\mathrm{e}^{2 \pi-x}-\mathrm{e}^{\mathrm{i} \theta} \mathrm{e}^{x}\right), \quad f \in \mathfrak{D}(A), \alpha \in \mathbb{C} . \tag{2.108}
\end{equation*}
$$

In particular, $f_{\theta}$ satisfies

$$
\begin{equation*}
f_{\theta}(2 \pi)=\mathrm{e}^{\mathrm{i} \tilde{\theta}} f_{\theta}(0), \quad \mathrm{e}^{\mathrm{i} \tilde{\theta}}=\frac{1-\mathrm{e}^{\mathrm{i} \theta} \mathrm{e}^{2 \pi}}{\mathrm{e}^{2 \pi}-\mathrm{e}^{\mathrm{i} \theta}}, \tag{2.109}
\end{equation*}
$$

and thus we have

$$
\begin{equation*}
\mathfrak{D}\left(A_{\theta}\right)=\left\{f \in H^{1}(0,2 \pi) \mid f(2 \pi)=\mathrm{e}^{\mathrm{i} \tilde{\theta}} f(0)\right\} . \tag{2.110}
\end{equation*}
$$

Concerning closures, we can combine the fact that a bounded operator is closed if and only if its domain is closed with item (iii) from Lemma 2.4 to obtain

Lemma 2.27. The following items are equivalent.

- $A$ is closed.
- $\mathfrak{D}(V)=\operatorname{Ran}(A+\mathrm{i})$ is closed.
- $\operatorname{Ran}(V)=\operatorname{Ran}(A-\mathrm{i})$ is closed.
- $V$ is closed.

Next, we give a useful criterion for the existence of self-adjoint extensions. A conjugate linear map $C: \mathfrak{H} \rightarrow \mathfrak{H}$ is called a conjugation if it satisfies $C^{2}=\mathbb{I}$ and $\langle C \psi, C \varphi\rangle=\langle\psi, \varphi\rangle$. The prototypical example is, of course, complex conjugation $C \psi=\psi^{*}$. An operator $A$ is called $C$-real if

$$
\begin{equation*}
C \mathfrak{D}(A) \subseteq \mathfrak{D}(A), \quad \text { and } \quad A C \psi=C A \psi, \quad \psi \in \mathfrak{D}(A) . \tag{2.111}
\end{equation*}
$$

Note that in this case $C \mathfrak{D}(A)=\mathfrak{D}(A)$, since $\mathfrak{D}(A)=C^{2} \mathfrak{D}(A) \subseteq C \mathfrak{D}(A)$.
Theorem 2.28. Suppose the symmetric operator $A$ is $C$-real. Then its defect indices are equal.

Proof. Let $\left\{\varphi_{j}\right\}$ be an orthonormal set in $\operatorname{Ran}(A+\mathrm{i})^{\perp}$. Then $\left\{C \varphi_{j}\right\}$ is an orthonormal set in $\operatorname{Ran}(A-i)^{\perp}$. Hence $\left\{\varphi_{j}\right\}$ is an orthonormal basis for $\operatorname{Ran}(A+\mathrm{i})^{\perp}$ if and only if $\left\{C \varphi_{j}\right\}$ is an orthonormal basis for $\operatorname{Ran}(A-\mathrm{i})^{\perp}$. Hence the two spaces have the same dimension.

Finally, we note the following useful formula for the difference of resolvents of self-adjoint extensions.

Lemma 2.29. If $A_{j}, j=1,2$, are self-adjoint extensions of $A$ and if $\left\{\varphi_{j}(z)\right\}$ is an orthonormal basis for $\operatorname{Ker}\left(A^{*}-z\right)$, then

$$
\begin{equation*}
\left(A_{1}-z\right)^{-1}-\left(A_{2}-z\right)^{-1}=\sum_{j, k}\left(\alpha_{j k}^{1}(z)-\alpha_{j k}^{2}(z)\right)\left\langle\varphi_{j}\left(z^{*}\right), .\right\rangle \varphi_{k}(z), \tag{2.112}
\end{equation*}
$$

where

$$
\begin{equation*}
\alpha_{j k}^{l}(z)=\left\langle\varphi_{k}(z),\left(A_{l}-z\right)^{-1} \varphi_{j}\left(z^{*}\right)\right\rangle . \tag{2.113}
\end{equation*}
$$

Proof. First observe that $\left(\left(A_{1}-z\right)^{-1}-\left(A_{2}-z\right)^{-1}\right) \varphi$ is zero for every $\varphi \in \operatorname{Ran}(A-z)$. Hence it suffices to consider vectors of the form $\varphi=$ $\sum_{j}\left\langle\varphi_{j}\left(z^{*}\right), \varphi\right\rangle \varphi_{j}\left(z^{*}\right) \in \operatorname{Ran}(A-z)^{\perp}=\operatorname{Ker}\left(A^{*}-z^{*}\right)$. Hence we have

$$
\left(A_{1}-z\right)^{-1}-\left(A_{2}-z\right)^{-1}=\sum_{j}\left\langle\varphi_{j}\left(z^{*}\right), .\right\rangle \psi_{j}(z),
$$

where

$$
\psi_{j}(z)=\left(\left(A_{1}-z\right)^{-1}-\left(A_{2}-z\right)^{-1}\right) \varphi_{j}\left(z^{*}\right) .
$$

Now computing the adjoint once using $\left(\left(A_{l}-z\right)^{-1}\right)^{*}=\left(A_{l}-z^{*}\right)^{-1}$ and once $\operatorname{using}\left(\sum_{j}\left\langle\varphi_{j}, .\right\rangle \psi_{j}\right)^{*}=\sum_{j}\left\langle\psi_{j},.\right\rangle \varphi_{j}$, we obtain

$$
\sum_{j}\left\langle\varphi_{j}(z), .\right\rangle \psi_{j}\left(z^{*}\right)=\sum_{j}\left\langle\psi_{j}(z), .\right\rangle \varphi_{k}\left(z^{*}\right) .
$$

Evaluating at $\varphi_{k}(z)$ implies

$$
\psi_{k}(z)=\sum_{j}\left\langle\psi_{j}\left(z^{*}\right), \varphi_{k}\left(z^{*}\right)\right\rangle \varphi_{j}(z)=\sum_{j}\left(\alpha_{k j}^{1}(z)-\alpha_{k j}^{2}(z)\right) \varphi_{j}(z)
$$

and finishes the proof.
Problem 2.27. Compute the defect indices of

$$
A_{0}=\mathrm{i} \frac{d}{d x}, \quad \mathfrak{D}\left(A_{0}\right)=C_{c}^{\infty}((0, \infty))
$$

Can you give a self-adjoint extension of $A_{0}$ ?
Problem 2.28. Let $A_{1}$ be a self-adjoint extension of $A$ and suppose $\varphi \in$ $\operatorname{Ker}\left(A^{*}-z_{0}\right)$. Show that $\varphi(z)=\varphi+\left(z-z_{0}\right)\left(A_{1}-z\right)^{-1} \varphi \in \operatorname{Ker}\left(A^{*}-z\right)$.

### 2.7. Appendix: Absolutely continuous functions

Let $(a, b) \subseteq \mathbb{R}$ be some interval. We denote by

$$
\begin{equation*}
A C(a, b)=\left\{f \in C(a, b) \mid f(x)=f(c)+\int_{c}^{x} g(t) d t, c \in(a, b), g \in L_{l o c}^{1}(a, b)\right\} \tag{2.114}
\end{equation*}
$$

the set of all absolutely continuous functions. That is, $f$ is absolutely continuous if and only if it can be written as the integral of some locally integrable function. Note that $A C(a, b)$ is a vector space.

By Corollary A.36, $f(x)=f(c)+\int_{c}^{x} g(t) d t$ is differentiable a.e. (with respect to Lebesgue measure) and $f^{\prime}(x)=g(x)$. In particular, $g$ is determined uniquely a.e.

If $[a, b]$ is a compact interval, we set

$$
\begin{equation*}
A C[a, b]=\left\{f \in A C(a, b) \mid g \in L^{1}(a, b)\right\} \subseteq C[a, b] . \tag{2.115}
\end{equation*}
$$

If $f, g \in A C[a, b]$, we have the formula of partial integration (Problem 2.29)

$$
\begin{equation*}
\int_{a}^{b} f(x) g^{\prime}(x) d x=f(b) g(b)-f(a) g(a)-\int_{a}^{b} f^{\prime}(x) g(x) d x \tag{2.116}
\end{equation*}
$$

which also implies that the product rule holds for absolutely continuous functions.

We set
$H^{m}(a, b)=\left\{f \in L^{2}(a, b) \mid f^{(j)} \in A C(a, b), f^{(j+1)} \in L^{2}(a, b), 0 \leq j \leq m-1\right\}$.
Then we have
Lemma 2.30. Suppose $f \in H^{m}(a, b), m \geq 1$. Then $f$ is bounded and $\lim _{x \downarrow a} f^{(j)}(x)$, respectively, $\lim _{x \uparrow b} f^{(j)}(x)$, exists for $0 \leq j \leq m-1$. Moreover, the limit is zero if the endpoint is infinite.

Proof. If the endpoint is finite, then $f^{(j+1)}$ is integrable near this endpoint and hence the claim follows. If the endpoint is infinite, note that

$$
\left|f^{(j)}(x)\right|^{2}=\left|f^{(j)}(c)\right|^{2}+2 \int_{c}^{x} \operatorname{Re}\left(f^{(j)}(t)^{*} f^{(j+1)}(t)\right) d t
$$

shows that the limit exists (dominated convergence). Since $f^{(j)}$ is square integrable, the limit must be zero.

Let me remark that it suffices to check that the function plus the highest derivative are in $L^{2}$; the lower derivatives are then automatically in $L^{2}$. That is,

$$
\begin{equation*}
H^{m}(a, b)=\left\{f \in L^{2}(a, b) \mid f^{(j)} \in A C(a, b), 0 \leq j \leq m-1, f^{(m)} \in L^{2}(a, b)\right\} \tag{2.118}
\end{equation*}
$$

For a finite endpoint this is straightforward. For an infinite endpoint this can also be shown directly, but it is much easier to use the Fourier transform (compare Section 7.1).
Problem 2.29. Show (2.116). (Hint: Fubini.)
Problem 2.30. A function $u \in L^{1}(0,1)$ is called weakly differentiable if for some $v \in L^{1}(0,1)$ we have

$$
\int_{0}^{1} v(x) \varphi(x) d x=-\int_{0}^{1} u(x) \varphi^{\prime}(x) d x
$$

for all test functions $\varphi \in C_{c}^{\infty}(0,1)$. Show that $u$ is weakly differentiable if and only if $u$ is absolutely continuous and $u^{\prime}=v$ in this case. (Hint: You will
need that $\int_{0}^{1} u(t) \varphi^{\prime}(t) d t=0$ for all $\varphi \in C_{c}^{\infty}(0,1)$ if and only if $f$ is constant. To see this choose some $\varphi_{0} \in C_{c}^{\infty}(0,1)$ with $I\left(\varphi_{0}\right)=\int_{0}^{1} \varphi_{0}(t) d t=1$. Then invoke Lemma 0.37 and use that every $\varphi \in C_{c}^{\infty}(0,1)$ can be written as $\varphi(t)=\Phi^{\prime}(t)+I(\varphi) \varphi_{0}(t)$ with $\left.\Phi(t)=\int_{0}^{t} \varphi(s) d s-I(\varphi) \int_{0}^{t} \varphi_{0}(s) d s.\right)$
Problem 2.31. Show that $H^{1}(a, b)$ together with the norm

$$
\|f\|_{2,1}^{2}=\int_{a}^{b}|f(t)|^{2} d t+\int_{a}^{b}\left|f^{\prime}(t)\right|^{2} d t
$$

is a Hilbert space.
Problem 2.32. What is the closure of $C_{0}^{\infty}(a, b)$ in $H^{1}(a, b)$ ? (Hint: Start with the case where ( $a, b$ ) is finite.)

Problem 2.33. Show that if $f \in A C(a, b)$ and $f^{\prime} \in L^{p}(a, b)$, then $f$ is Hölder continuous:

$$
|f(x)-f(y)| \leq\left\|f^{\prime}\right\|_{p}|x-y|^{1-\frac{1}{p}}
$$

## The spectral theorem

The time evolution of a quantum mechanical system is governed by the Schrödinger equation

$$
\begin{equation*}
\mathrm{i} \frac{d}{d t} \psi(t)=H \psi(t) \tag{3.1}
\end{equation*}
$$

If $\mathfrak{H}=\mathbb{C}^{n}$ and $H$ is hence a matrix, this system of ordinary differential equations is solved by the matrix exponential

$$
\begin{equation*}
\psi(t)=\exp (-\mathrm{i} t H) \psi(0) . \tag{3.2}
\end{equation*}
$$

This matrix exponential can be defined by a convergent power series

$$
\begin{equation*}
\exp (-\mathrm{i} t H)=\sum_{n=0}^{\infty} \frac{(-\mathrm{i} t)^{n}}{n!} H^{n} . \tag{3.3}
\end{equation*}
$$

For this approach the boundedness of $H$ is crucial, which might not be the case for a quantum system. However, the best way to compute the matrix exponential and to understand the underlying dynamics is to diagonalize $H$. But how do we diagonalize a self-adjoint operator? The answer is known as the spectral theorem.

### 3.1. The spectral theorem

In this section we want to address the problem of defining functions of a self-adjoint operator $A$ in a natural way, that is, such that

$$
\begin{equation*}
(f+g)(A)=f(A)+g(A), \quad(f g)(A)=f(A) g(A), \quad\left(f^{*}\right)(A)=f(A)^{*} \tag{3.4}
\end{equation*}
$$

As long as $f$ and $g$ are polynomials, no problems arise. If we want to extend this definition to a larger class of functions, we will need to perform some limiting procedure. Hence we could consider convergent power series or equip the space of polynomials on the spectrum with the sup norm. In both
cases this only works if the operator $A$ is bounded. To overcome this limitation, we will use characteristic functions $\chi_{\Omega}(A)$ instead of powers $A^{j}$. Since $\chi_{\Omega}(\lambda)^{2}=\chi_{\Omega}(\lambda)$, the corresponding operators should be orthogonal projections. Moreover, we should also have $\chi_{\mathbb{R}}(A)=\mathbb{I}$ and $\chi_{\Omega}(A)=\sum_{j=1}^{n} \chi_{\Omega_{j}}(A)$ for any finite union $\Omega=\bigcup_{j=1}^{n} \Omega_{j}$ of disjoint sets. The only remaining problem is of course the definition of $\chi_{\Omega}(A)$. However, we will defer this problem and begin by developing a functional calculus for a family of characteristic functions $\chi_{\Omega}(A)$.

Denote the Borel sigma algebra of $\mathbb{R}$ by $\mathfrak{B}$. A projection-valued measure is a map

$$
\begin{equation*}
P: \mathfrak{B} \rightarrow \mathfrak{L}(\mathfrak{H}), \quad \Omega \mapsto P(\Omega), \tag{3.5}
\end{equation*}
$$

from the Borel sets to the set of orthogonal projections, that is, $P(\Omega)^{*}=$ $P(\Omega)$ and $P(\Omega)^{2}=P(\Omega)$, such that the following two conditions hold:
(i) $P(\mathbb{R})=\mathbb{I}$.
(ii) If $\Omega=\bigcup_{n} \Omega_{n}$ with $\Omega_{n} \cap \Omega_{m}=\emptyset$ for $n \neq m$, then $\sum_{n} P\left(\Omega_{n}\right) \psi=$ $P(\Omega) \psi$ for every $\psi \in \mathfrak{H}$ (strong $\sigma$-additivity).
Note that we require strong convergence, $\sum_{n} P\left(\Omega_{n}\right) \psi=P(\Omega) \psi$, rather than norm convergence, $\sum_{n} P\left(\Omega_{n}\right)=P(\Omega)$. In fact, norm convergence does not even hold in the simplest case where $\mathfrak{H}=L^{2}(I)$ and $P(\Omega)=\chi_{\Omega}$ (multiplication operator), since for a multiplication operator the norm is just the sup norm of the function. Furthermore, it even suffices to require weak convergence, since w-lim $P_{n}=P$ for some orthogonal projections implies s-lim $P_{n}=P$ by $\left\langle\psi, P_{n} \psi\right\rangle=\left\langle\psi, P_{n}^{2} \psi\right\rangle=\left\langle P_{n} \psi, P_{n} \psi\right\rangle=\left\|P_{n} \psi\right\|^{2}$ together with Lemma 1.12 (iv).
Example. Let $\mathfrak{H}=\mathbb{C}^{n}$ and let $A \in \mathrm{GL}(n)$ be some symmetric matrix. Let $\lambda_{1}, \ldots, \lambda_{m}$ be its (distinct) eigenvalues and let $P_{j}$ be the projections onto the corresponding eigenspaces. Then

$$
\begin{equation*}
P_{A}(\Omega)=\sum_{\left\{j \mid \lambda_{j} \in \Omega\right\}} P_{j} \tag{3.6}
\end{equation*}
$$

is a projection-valued measure.
Example. Let $\mathfrak{H}=L^{2}(\mathbb{R})$ and let $f$ be a real-valued measurable function. Then

$$
\begin{equation*}
P(\Omega)=\chi_{f^{-1}(\Omega)} \tag{3.7}
\end{equation*}
$$

is a projection-valued measure (Problem 3.3).
It is straightforward to verify that any projection-valued measure satisfies

$$
\begin{equation*}
P(\not \emptyset)=0, \quad P(\mathbb{R} \backslash \Omega)=\mathbb{I}-P(\Omega) \tag{3.8}
\end{equation*}
$$

and

$$
\begin{equation*}
P\left(\Omega_{1} \cup \Omega_{2}\right)+P\left(\Omega_{1} \cap \Omega_{2}\right)=P\left(\Omega_{1}\right)+P\left(\Omega_{2}\right) \tag{3.9}
\end{equation*}
$$

Moreover, we also have

$$
\begin{equation*}
P\left(\Omega_{1}\right) P\left(\Omega_{2}\right)=P\left(\Omega_{1} \cap \Omega_{2}\right) . \tag{3.10}
\end{equation*}
$$

Indeed, first suppose $\Omega_{1} \cap \Omega_{2}=\emptyset$. Then, taking the square of (3.9), we infer

$$
\begin{equation*}
P\left(\Omega_{1}\right) P\left(\Omega_{2}\right)+P\left(\Omega_{2}\right) P\left(\Omega_{1}\right)=0 \tag{3.11}
\end{equation*}
$$

Multiplying this equation from the right by $P\left(\Omega_{2}\right)$ shows that $P\left(\Omega_{1}\right) P\left(\Omega_{2}\right)=$ $-P\left(\Omega_{2}\right) P\left(\Omega_{1}\right) P\left(\Omega_{2}\right)$ is self-adjoint and thus $P\left(\Omega_{1}\right) P\left(\Omega_{2}\right)=P\left(\Omega_{2}\right) P\left(\Omega_{1}\right)=$ 0 . For the general case $\Omega_{1} \cap \Omega_{2} \neq \emptyset$ we now have

$$
\begin{align*}
P\left(\Omega_{1}\right) P\left(\Omega_{2}\right) & =\left(P\left(\Omega_{1}-\Omega_{2}\right)+P\left(\Omega_{1} \cap \Omega_{2}\right)\right)\left(P\left(\Omega_{2}-\Omega_{1}\right)+P\left(\Omega_{1} \cap \Omega_{2}\right)\right) \\
& =P\left(\Omega_{1} \cap \Omega_{2}\right) \tag{3.12}
\end{align*}
$$

as stated.
Moreover, a projection-valued measure is monotone, that is,

$$
\begin{equation*}
\Omega_{1} \subseteq \Omega_{2} \quad \Rightarrow \quad P\left(\Omega_{1}\right) \leq P\left(\Omega_{2}\right), \tag{3.13}
\end{equation*}
$$

in the sense that $\left\langle\psi, P\left(\Omega_{1}\right) \psi\right\rangle \leq\left\langle\psi, P\left(\Omega_{2}\right) \psi\right\rangle$ or equivalently $\operatorname{Ran}\left(P\left(\Omega_{1}\right)\right) \subseteq$ $\operatorname{Ran}\left(P\left(\Omega_{2}\right)\right)$ (cf. Problem 1.7). As a useful consequence note that $P\left(\Omega_{2}\right)=0$ implies $P\left(\Omega_{1}\right)=0$ for every subset $\Omega_{1} \subseteq \Omega_{2}$.

To every projection-valued measure there corresponds a resolution of the identity

$$
\begin{equation*}
P(\lambda)=P((-\infty, \lambda]) \tag{3.14}
\end{equation*}
$$

which has the properties (Problem 3.4):
(i) $P(\lambda)$ is an orthogonal projection.
(ii) $P\left(\lambda_{1}\right) \leq P\left(\lambda_{2}\right)$ for $\lambda_{1} \leq \lambda_{2}$.
(iii) $\mathrm{s}-\lim _{\lambda_{n} \downarrow \lambda} P\left(\lambda_{n}\right)=P(\lambda)$ (strong right continuity).
(iv) $s-\lim _{\lambda \rightarrow-\infty} P(\lambda)=0$ and $s-\lim _{\lambda \rightarrow+\infty} P(\lambda)=\mathbb{I}$.

As before, strong right continuity is equivalent to weak right continuity.
Picking $\psi \in \mathfrak{H}$, we obtain a finite Borel measure $\mu_{\psi}(\Omega)=\langle\psi, P(\Omega) \psi\rangle=$ $\|P(\Omega) \psi\|^{2}$ with $\mu_{\psi}(\mathbb{R})=\|\psi\|^{2}<\infty$. The corresponding distribution function is given by $\mu_{\psi}(\lambda)=\langle\psi, P(\lambda) \psi\rangle$ and since for every distribution function there is a unique Borel measure (Theorem A.2), for every resolution of the identity there is a unique projection-valued measure.

Using the polarization identity (2.16), we also have the complex Borel measures

$$
\begin{equation*}
\mu_{\varphi, \psi}(\Omega)=\langle\varphi, P(\Omega) \psi\rangle=\frac{1}{4}\left(\mu_{\varphi+\psi}(\Omega)-\mu_{\varphi-\psi}(\Omega)+\mathrm{i} \mu_{\varphi-\mathrm{i} \psi}(\Omega)-\mathrm{i} \mu_{\varphi+\mathrm{i} \psi}(\Omega)\right) . \tag{3.15}
\end{equation*}
$$

Note also that, by Cauchy-Schwarz, $\left|\mu_{\varphi, \psi}(\Omega)\right| \leq\|\varphi\|\|\psi\|$.

Now let us turn to integration with respect to our projection-valued measure. For any simple function $f=\sum_{j=1}^{n} \alpha_{j} \chi_{\Omega_{j}}$ (where $\left.\Omega_{j}=f^{-1}\left(\alpha_{j}\right)\right)$ we set

$$
\begin{equation*}
P(f) \equiv \int_{\mathbb{R}} f(\lambda) d P(\lambda)=\sum_{j=1}^{n} \alpha_{j} P\left(\Omega_{j}\right) \tag{3.16}
\end{equation*}
$$

In particular, $P\left(\chi_{\Omega}\right)=P(\Omega)$. Then $\langle\varphi, P(f) \psi\rangle=\sum_{j} \alpha_{j} \mu_{\varphi, \psi}\left(\Omega_{j}\right)$ shows

$$
\begin{equation*}
\langle\varphi, P(f) \psi\rangle=\int_{\mathbb{R}} f(\lambda) d \mu_{\varphi, \psi}(\lambda) \tag{3.17}
\end{equation*}
$$

and, by linearity of the integral, the operator $P$ is a linear map from the set of simple functions into the set of bounded linear operators on $\mathfrak{H}$. Moreover, $\|P(f) \psi\|^{2}=\sum_{j}\left|\alpha_{j}\right|^{2} \mu_{\psi}\left(\Omega_{j}\right)$ (the sets $\Omega_{j}$ are disjoint) shows

$$
\begin{equation*}
\|P(f) \psi\|^{2}=\int_{\mathbb{R}}|f(\lambda)|^{2} d \mu_{\psi}(\lambda) \tag{3.18}
\end{equation*}
$$

Equipping the set of simple functions with the sup norm, we infer

$$
\begin{equation*}
\|P(f) \psi\| \leq\|f\|_{\infty}\|\psi\|, \tag{3.19}
\end{equation*}
$$

which implies that $P$ has norm one. Since the simple functions are dense in the Banach space of bounded Borel functions $B(\mathbb{R})$, there is a unique extension of $P$ to a bounded linear operator $P: B(\mathbb{R}) \rightarrow \mathfrak{L}(\mathfrak{H})$ (whose norm is one) from the bounded Borel functions on $\mathbb{R}$ (with sup norm) to the set of bounded linear operators on $\mathfrak{H}$. In particular, (3.17) and (3.18) remain true.

There is some additional structure behind this extension. Recall that the set $\mathfrak{L}(\mathfrak{H})$ of all bounded linear mappings on $\mathfrak{H}$ forms a $C^{*}$ algebra. A $C^{*}$ algebra homomorphism $\phi$ is a linear map between two $C^{*}$ algebras which respects both the multiplication and the adjoint; that is, $\phi(a b)=\phi(a) \phi(b)$ and $\phi\left(a^{*}\right)=\phi(a)^{*}$.

Theorem 3.1. Let $P(\Omega)$ be a projection-valued measure on $\mathfrak{H}$. Then the operator

$$
\begin{align*}
P: & B(\mathbb{R})
\end{align*} \rightarrow \mathfrak{L}(\mathfrak{H})=\left\{\begin{array}{l}
f  \tag{3.20}\\
f
\end{array}\right) \mapsto \int_{\mathbb{R}} f(\lambda) d P(\lambda)
$$

is a $C^{*}$ algebra homomorphism with norm one such that

$$
\begin{equation*}
\langle P(g) \varphi, P(f) \psi\rangle=\int_{\mathbb{R}} g^{*}(\lambda) f(\lambda) d \mu_{\varphi, \psi}(\lambda) \tag{3.21}
\end{equation*}
$$

In addition, if $f_{n}(x) \rightarrow f(x)$ pointwise and if the sequence $\sup _{\lambda \in \mathbb{R}}\left|f_{n}(\lambda)\right|$ is bounded, then $P\left(f_{n}\right) \xrightarrow{s} P(f)$ strongly.

Proof. The properties $P(1)=\mathbb{I}, P\left(f^{*}\right)=P(f)^{*}$, and $P(f g)=P(f) P(g)$ are straightforward for simple functions $f$. For general $f$ they follow from continuity. Hence $P$ is a $C^{*}$ algebra homomorphism.

Equation (3.21) is a consequence of $\langle P(g) \varphi, P(f) \psi\rangle=\left\langle\varphi, P\left(g^{*} f\right) \psi\right\rangle$.
The last claim follows from the dominated convergence theorem and (3.18).

As a consequence of (3.21), observe

$$
\begin{equation*}
\mu_{P(g) \varphi, P(f) \psi}(\Omega)=\langle P(g) \varphi, P(\Omega) P(f) \psi\rangle=\int_{\Omega} g^{*}(\lambda) f(\lambda) d \mu_{\varphi, \psi}(\lambda) \tag{3.22}
\end{equation*}
$$

which implies

$$
\begin{equation*}
d \mu_{P(g) \varphi, P(f) \psi}=g^{*} f d \mu_{\varphi, \psi} \tag{3.23}
\end{equation*}
$$

Example. Let $\mathfrak{H}=\mathbb{C}^{n}$ and $A=A^{*} \in \mathrm{GL}(n)$, respectively, $P_{A}$, as in the previous example. Then

$$
\begin{equation*}
P_{A}(f)=\sum_{j=1}^{m} f\left(\lambda_{j}\right) P_{j} . \tag{3.24}
\end{equation*}
$$

In particular, $P_{A}(f)=A$ for $f(\lambda)=\lambda$.
Next we want to define this operator for unbounded Borel functions. Since we expect the resulting operator to be unbounded, we need a suitable domain first. Motivated by (3.18), we set

$$
\begin{equation*}
\mathfrak{D}_{f}=\left\{\left.\psi \in \mathfrak{H}\left|\int_{\mathbb{R}}\right| f(\lambda)\right|^{2} d \mu_{\psi}(\lambda)<\infty\right\} . \tag{3.25}
\end{equation*}
$$

This is clearly a linear subspace of $\mathfrak{H}$ since $\mu_{\alpha \psi}(\Omega)=|\alpha|^{2} \mu_{\psi}(\Omega)$ and since $\mu_{\varphi+\psi}(\Omega)=\|P(\Omega)(\varphi+\psi)\|^{2} \leq 2\left(\|P(\Omega) \varphi\|^{2}+\|P(\Omega) \psi\|^{2}\right)=2\left(\mu_{\varphi}(\Omega)+\mu_{\psi}(\Omega)\right)$ (by the triangle inequality).

For every $\psi \in \mathfrak{D}_{f}$, the sequence of bounded Borel functions

$$
\begin{equation*}
f_{n}=\chi_{\Omega_{n}} f, \quad \Omega_{n}=\{\lambda| | f(\lambda) \mid \leq n\}, \tag{3.26}
\end{equation*}
$$

is a Cauchy sequence converging to $f$ in the sense of $L^{2}\left(\mathbb{R}, d \mu_{\psi}\right)$. Hence, by virtue of (3.18), the vectors $\psi_{n}=P\left(f_{n}\right) \psi$ form a Cauchy sequence in $\mathfrak{H}$ and we can define

$$
\begin{equation*}
P(f) \psi=\lim _{n \rightarrow \infty} P\left(f_{n}\right) \psi, \quad \psi \in \mathfrak{D}_{f} \tag{3.27}
\end{equation*}
$$

By construction, $P(f)$ is a linear operator such that (3.18) holds. Since $f \in L^{1}\left(\mathbb{R}, d \mu_{\psi}\right)$ ( $\mu_{\psi}$ is finite), (3.17) also remains true at least for $\varphi=\psi$.

In addition, $\mathfrak{D}_{f}$ is dense. Indeed, let $\Omega_{n}$ be defined as in (3.26) and abbreviate $\psi_{n}=P\left(\Omega_{n}\right) \psi$. Now observe that $d \mu_{\psi_{n}}=\chi_{\Omega_{n}} d \mu_{\psi}$ and hence $\psi_{n} \in \mathfrak{D}_{f}$. Moreover, $\psi_{n} \rightarrow \psi$ by (3.18) since $\chi_{\Omega_{n}} \rightarrow 1$ in $L^{2}\left(\mathbb{R}, d \mu_{\psi}\right)$.

The operator $P(f)$ has some additional properties. One calls an unbounded operator $A$ normal if $\mathfrak{D}(A)=\mathfrak{D}\left(A^{*}\right)$ and $\|A \psi\|=\left\|A^{*} \psi\right\|$ for all $\psi \in \mathfrak{D}(A)$. Note that normal operators are closed since the graph norms on $\mathfrak{D}(A)=\mathfrak{D}\left(A^{*}\right)$ are identical.

Theorem 3.2. For any Borel function $f$, the operator

$$
\begin{equation*}
P(f) \equiv \int_{\mathbb{R}} f(\lambda) d P(\lambda), \quad \mathfrak{D}(P(f))=\mathfrak{D}_{f} \tag{3.28}
\end{equation*}
$$

is normal and satisfies

$$
\begin{equation*}
P(f)^{*}=P\left(f^{*}\right) . \tag{3.29}
\end{equation*}
$$

Proof. Let $f$ be given and define $f_{n}, \Omega_{n}$ as above. Since (3.29) holds for $f_{n}$ by our previous theorem, we get

$$
\langle\varphi, P(f) \psi\rangle=\left\langle P\left(f^{*}\right) \varphi, \psi\right\rangle
$$

for any $\varphi, \psi \in \mathfrak{D}_{f}=\mathfrak{D}_{f^{*}}$ by continuity. Thus it remains to show that $\mathfrak{D}\left(P(f)^{*}\right) \subseteq \mathfrak{D}_{f}$. If $\psi \in \mathfrak{D}\left(P(f)^{*}\right)$, we have $\langle\psi, P(f) \varphi\rangle=\langle\tilde{\psi}, \varphi\rangle$ for all $\varphi \in \mathfrak{D}_{f}$ by definition. By construction of $P(f)$ we have $P\left(f_{n}\right)=P(f) P\left(\Omega_{n}\right)$ and thus

$$
\left\langle P\left(f_{n}^{*}\right) \psi, \varphi\right\rangle=\left\langle\psi, P\left(f_{n}\right) \varphi\right\rangle=\left\langle\psi, P(f) P\left(\Omega_{n}\right) \varphi\right\rangle=\left\langle P\left(\Omega_{n}\right) \tilde{\psi}, \varphi\right\rangle
$$

for any $\varphi \in \mathfrak{H}$ shows $P\left(f_{n}^{*}\right) \psi=P\left(\Omega_{n}\right) \tilde{\psi}$. This proves existence of the limit

$$
\lim _{n \rightarrow \infty} \int_{\mathbb{R}}\left|f_{n}\right|^{2} d \mu_{\psi}=\lim _{n \rightarrow \infty}\left\|P\left(f_{n}^{*}\right) \psi\right\|^{2}=\lim _{n \rightarrow \infty}\left\|P\left(\Omega_{n}\right) \tilde{\psi}\right\|^{2}=\|\tilde{\psi}\|^{2},
$$

which by monotone convergence implies $f \in L^{2}\left(\mathbb{R}, d \mu_{\psi}\right)$; that is, $\psi \in \mathfrak{D}_{f}$.
That $P(f)$ is normal follows from (3.18), which implies $\|P(f) \psi\|^{2}=$ $\left\|P\left(f^{*}\right) \psi\right\|^{2}=\int_{\mathbb{R}}|f(\lambda)|^{2} d \mu_{\psi}$.

These considerations seem to indicate some kind of correspondence between the operators $P(f)$ in $\mathfrak{H}$ and $f$ in $L^{2}\left(\mathbb{R}, d \mu_{\psi}\right)$. Recall that $U: \mathfrak{H} \rightarrow \tilde{\mathfrak{H}}$ is called unitary if it is a bijection which preserves norms $\|U \psi\|=\|\psi\|$ (and hence scalar products). The operators $A$ in $\mathfrak{H}$ and $\tilde{A}$ in $\tilde{\mathfrak{H}}$ are said to be unitarily equivalent if

$$
\begin{equation*}
U A=\tilde{A} U, \quad U \mathfrak{D}(A)=\mathfrak{D}(\tilde{A}) . \tag{3.30}
\end{equation*}
$$

Clearly, $A$ is self-adjoint if and only if $\tilde{A}$ is and $\sigma(A)=\sigma(\tilde{A})$.
Now let us return to our original problem and consider the subspace

$$
\begin{equation*}
\mathfrak{H}_{\psi}=\left\{P(g) \psi \mid g \in L^{2}\left(\mathbb{R}, d \mu_{\psi}\right)\right\} \subseteq \mathfrak{H} . \tag{3.31}
\end{equation*}
$$

Note that $\mathfrak{H}_{\psi}$ is closed since $L^{2}$ is and $\psi_{n}=P\left(g_{n}\right) \psi$ converges in $\mathfrak{H}$ if and only if $g_{n}$ converges in $L^{2}$. It even turns out that we can restrict $P(f)$ to $\mathfrak{H}_{\psi}$ (see Section 2.5).

Lemma 3.3. The subspace $\mathfrak{H}_{\psi}$ reduces $P(f)$; that is, $P_{\psi} P(f) \subseteq P(f) P_{\psi}$. Here $P_{\psi}$ is the projection onto $\mathfrak{H}_{\psi}$.

Proof. First suppose $f$ is bounded. Any $\varphi \in \mathfrak{H}$ can be decomposed as $\varphi=P(g) \psi+\varphi^{\perp}$. Moreover, $\left\langle P(h) \psi, P(f) \varphi^{\perp}\right\rangle=\left\langle P\left(f^{*} h\right) \psi, \varphi^{\perp}\right\rangle=0$ for every bounded function $h$ implies $P(f) \varphi^{\perp} \in \mathfrak{H}_{\psi}^{\perp}$. Hence $P_{\psi} P(f) \varphi=$ $P_{\psi} P(f) P(g) \psi=P(f) P_{\psi} \varphi$ which by definition says that $\mathfrak{H}_{\psi}$ reduces $P(f)$.

If $f$ is unbounded, we consider $f_{n}=f \chi_{\Omega_{n}}$ as before. Then, for every $\varphi \in \mathfrak{D}_{f}, P\left(f_{n}\right) P_{\psi} \varphi=P_{\psi} P\left(f_{n}\right) \varphi$. Letting $n \rightarrow \infty$, we have $P\left(\Omega_{n}\right) P_{\psi} \varphi \rightarrow$ $P_{\psi} \varphi$ and $P\left(f_{n}\right) P_{\psi} \varphi=P(f) P\left(\Omega_{n}\right) P_{\psi} \varphi \rightarrow P_{\psi} P(f) \varphi$. Finally, closedness of $P(f)$ implies $P_{\psi} \varphi \in \mathfrak{D}_{f}$ and $P(f) P_{\psi} \varphi=P_{\psi} P(f) \varphi$.

In particular we can decompose $P(f)=\left.\left.P(f)\right|_{\mathfrak{H}_{\psi}} \oplus P(f)\right|_{\mathfrak{H}_{\psi}^{\ddagger}}$. Note that

$$
\begin{equation*}
P_{\psi} \mathfrak{D}_{f}=\mathfrak{D}_{f} \cap \mathfrak{H}_{\psi}=\left\{P(g) \psi \mid g, f g \in L^{2}\left(\mathbb{R}, d \mu_{\psi}\right)\right\} \tag{3.32}
\end{equation*}
$$

and $P(f) P(g) \psi=P(f g) \psi \in \mathfrak{H}_{\psi}$ in this case.
By (3.18), the relation

$$
\begin{equation*}
U_{\psi}(P(f) \psi)=f \tag{3.33}
\end{equation*}
$$

defines a unique unitary operator $U_{\psi}: \mathfrak{H}_{\psi} \rightarrow L^{2}\left(\mathbb{R}, d \mu_{\psi}\right)$ such that

$$
\begin{equation*}
\left.U_{\psi} P(f)\right|_{\mathfrak{H}_{\psi}}=f U_{\psi}, \tag{3.34}
\end{equation*}
$$

where $f$ is identified with its corresponding multiplication operator. Moreover, if $f$ is unbounded, we have $U_{\psi}\left(\mathfrak{D}_{f} \cap \mathfrak{H}_{\psi}\right)=\mathfrak{D}(f)=\left\{g \in L^{2}\left(\mathbb{R}, d \mu_{\psi}\right) \mid f g \in\right.$ $\left.L^{2}\left(\mathbb{R}, d \mu_{\psi}\right)\right\}$ (since $\varphi=P(f) \psi$ implies $\left.d \mu_{\varphi}=|f|^{2} d \mu_{\psi}\right)$ and the above equation still holds.

The vector $\psi$ is called cyclic if $\mathfrak{H}_{\psi}=\mathfrak{H}$ and in this case our picture is complete. Otherwise we need to extend this approach. A set $\left\{\psi_{j}\right\}_{j \in J}(J$ some index set) is called a set of spectral vectors if $\left\|\psi_{j}\right\|=1$ and $\mathfrak{H}_{\psi_{i}} \perp \mathfrak{H}_{\psi_{j}}$ for all $i \neq j$. A set of spectral vectors is called a spectral basis if $\bigoplus_{j} \mathfrak{H}_{\psi_{j}}=$ $\mathfrak{H}$. Luckily a spectral basis always exists:

Lemma 3.4. For every projection-valued measure $P$, there is an (at most countable) spectral basis $\left\{\psi_{n}\right\}$ such that

$$
\begin{equation*}
\mathfrak{H}=\bigoplus_{n} \mathfrak{H}_{\psi_{n}} \tag{3.35}
\end{equation*}
$$

and a corresponding unitary operator

$$
\begin{equation*}
U=\bigoplus_{n} U_{\psi_{n}}: \mathfrak{H} \rightarrow \bigoplus_{n} L^{2}\left(\mathbb{R}, d \mu_{\psi_{n}}\right) \tag{3.36}
\end{equation*}
$$

such that for any Borel function $f$,

$$
\begin{equation*}
U P(f)=f U, \quad U \mathfrak{D}_{f}=\mathfrak{D}(f) \tag{3.37}
\end{equation*}
$$

Proof. It suffices to show that a spectral basis exists. This can be easily done using a Gram-Schmidt type construction. First of all observe that if $\left\{\psi_{j}\right\}_{j \in J}$ is a spectral set and $\psi \perp \mathfrak{H}_{\psi_{j}}$ for all $j$, we have $\mathfrak{H}_{\psi} \perp \mathfrak{H}_{\psi_{j}}$ for all $j$. Indeed, $\psi \perp \mathfrak{H}_{\psi_{j}}$ implies $P(g) \psi \perp \mathfrak{H}_{\psi_{j}}$ for every bounded function $g$ since $\left\langle P(g) \psi, P(f) \psi_{j}\right\rangle=\left\langle\psi, P\left(g^{*} f\right) \psi_{j}\right\rangle=0$. But $P(g) \psi$ with $g$ bounded is dense in $\mathfrak{H}_{\psi}$ implying $\mathfrak{H}_{\psi} \perp \mathfrak{H}_{\psi_{j}}$.

Now start with some total set $\left\{\tilde{\psi}_{j}\right\}$. Normalize $\tilde{\psi}_{1}$ and choose this to be $\psi_{1}$. Move to the first $\tilde{\psi}_{j}$ which is not in $\mathfrak{H}_{\psi_{1}}$, project to the orthogonal complement of $\mathfrak{H}_{\psi_{1}}$ and normalize it. Choose the result to be $\psi_{2}$. Proceeding like this, we get a set of spectral vectors $\left\{\psi_{j}\right\}$ such that $\operatorname{span}\left\{\tilde{\psi}_{j}\right\} \subseteq \bigoplus_{j} \mathfrak{H}_{\psi_{j}}$. Hence $\mathfrak{H}=\overline{\operatorname{span}\left\{\tilde{\psi}_{j}\right\}} \subseteq \bigoplus_{j} \mathfrak{H}_{\psi_{j}}$.

It is important to observe that the cardinality of a spectral basis is not well-defined (in contradistinction to the cardinality of an ordinary basis of the Hilbert space). However, it can be at most equal to the cardinality of an ordinary basis. In particular, since $\mathfrak{H}$ is separable, it is at most countable. The minimal cardinality of a spectral basis is called the spectral multiplicity of $P$. If the spectral multiplicity is one, the spectrum is called simple.
Example. Let $\mathfrak{H}=\mathbb{C}^{2}$ and $A=\left(\begin{array}{ll}0 & 0 \\ 0 & 1\end{array}\right)$ and consider the associated projectionvalued measure $P_{A}(\Omega)$ as before. Then $\psi_{1}=(1,0)$ and $\psi_{2}=(0,1)$ are a spectral basis. However, $\psi=(1,1)$ is cyclic and hence the spectrum of $A$ is simple. If $A=\left(\begin{array}{ll}1 & 0 \\ 0 & 1\end{array}\right)$, there is no cyclic vector (why?) and hence the spectral multiplicity is two.

Using this canonical form of projection-valued measures, it is straightforward to prove

Lemma 3.5. Let $f, g$ be Borel functions and $\alpha, \beta \in \mathbb{C}$. Then we have

$$
\begin{equation*}
\alpha P(f)+\beta P(g) \subseteq P(\alpha f+\beta g), \quad \mathfrak{D}(\alpha P(f)+\beta P(g))=\mathfrak{D}_{|f|+|g|} \tag{3.38}
\end{equation*}
$$

and

$$
\begin{equation*}
P(f) P(g) \subseteq P(f g), \quad \mathfrak{D}(P(f) P(g))=\mathfrak{D}_{g} \cap \mathfrak{D}_{f g} \tag{3.39}
\end{equation*}
$$

Now observe that to every projection-valued measure $P$ we can assign a self-adjoint operator $A=\int_{\mathbb{R}} \lambda d P(\lambda)$. The question is whether we can invert this map. To do this, we consider the resolvent $R_{A}(z)=\int_{\mathbb{R}}(\lambda-z)^{-1} d P(\lambda)$. From (3.17) the corresponding quadratic form is given by

$$
\begin{equation*}
F_{\psi}(z)=\left\langle\psi, R_{A}(z) \psi\right\rangle=\int_{\mathbb{R}} \frac{1}{\lambda-z} d \mu_{\psi}(\lambda), \tag{3.40}
\end{equation*}
$$

which is know as the Borel transform of the measure $\mu_{\psi}$. By

$$
\begin{equation*}
\operatorname{Im}\left(F_{\psi}(z)\right)=\operatorname{Im}(z) \int_{\mathbb{R}} \frac{1}{|\lambda-z|^{2}} d \mu_{\psi}(\lambda) \tag{3.41}
\end{equation*}
$$

we infer that $F_{\psi}(z)$ is a holomorphic map from the upper half plane into itself. Such functions are called Herglotz or Nevanlinna functions (see Section 3.4). Moreover, the measure $\mu_{\psi}$ can be reconstructed from $F_{\psi}(z)$ by the Stieltjes inversion formula

$$
\begin{equation*}
\mu_{\psi}(\lambda)=\lim _{\delta \downarrow 0} \lim _{\varepsilon \downarrow 0} \frac{1}{\pi} \int_{-\infty}^{\lambda+\delta} \operatorname{Im}\left(F_{\psi}(t+\mathrm{i} \varepsilon)\right) d t . \tag{3.42}
\end{equation*}
$$

(The limit with respect to $\delta$ is only here to ensure right continuity of $\mu_{\psi}(\lambda)$.) Conversely, if $F_{\psi}(z)$ is a Herglotz function satisfying $\left|F_{\psi}(z)\right| \leq \frac{M}{\operatorname{Im}(z)}$, then it is the Borel transform of a unique measure $\mu_{\psi}$ (given by the Stieltjes inversion formula) satisfying $\mu_{\psi}(\mathbb{R}) \leq M$.

So let $A$ be a given self-adjoint operator and consider the expectation of the resolvent of $A$,

$$
\begin{equation*}
F_{\psi}(z)=\left\langle\psi, R_{A}(z) \psi\right\rangle \tag{3.43}
\end{equation*}
$$

This function is holomorphic for $z \in \rho(A)$ and satisfies

$$
\begin{equation*}
F_{\psi}\left(z^{*}\right)=F_{\psi}(z)^{*} \quad \text { and } \quad\left|F_{\psi}(z)\right| \leq \frac{\|\psi\|^{2}}{\operatorname{Im}(z)} \tag{3.44}
\end{equation*}
$$

(see (2.69) and Theorem 2.18). Moreover, the first resolvent formula (2.81) shows that it maps the upper half plane to itself:

$$
\begin{equation*}
\operatorname{Im}\left(F_{\psi}(z)\right)=\operatorname{Im}(z)\left\|R_{A}(z) \psi\right\|^{2} \tag{3.45}
\end{equation*}
$$

that is, it is a Herglotz function. So by our above remarks, there is a corresponding measure $\mu_{\psi}(\lambda)$ given by the Stieltjes inversion formula. It is called the spectral measure corresponding to $\psi$.

More generally, by polarization, for each $\varphi, \psi \in \mathfrak{H}$ we can find a corresponding complex measure $\mu_{\varphi, \psi}$ such that

$$
\begin{equation*}
\left\langle\varphi, R_{A}(z) \psi\right\rangle=\int_{\mathbb{R}} \frac{1}{\lambda-z} d \mu_{\varphi, \psi}(\lambda) \tag{3.46}
\end{equation*}
$$

The measure $\mu_{\varphi, \psi}$ is conjugate linear in $\varphi$ and linear in $\psi$. Moreover, a comparison with our previous considerations begs us to define a family of operators via the sesquilinear forms

$$
\begin{equation*}
s_{\Omega}(\varphi, \psi)=\int_{\mathbb{R}} \chi_{\Omega}(\lambda) d \mu_{\varphi, \psi}(\lambda) . \tag{3.47}
\end{equation*}
$$

Since the associated quadratic form is nonnegative, $q_{\Omega}(\psi)=s_{\Omega}(\psi, \psi)=$ $\mu_{\psi}(\Omega) \geq 0$, the Cauchy-Schwarz inequality for sesquilinear forms (Problem 0.16) implies $\left|s_{\Omega}(\varphi, \psi)\right| \leq q_{\Omega}(\varphi)^{1 / 2} q_{\Omega}(\psi)^{1 / 2}=\mu_{\varphi}(\Omega)^{1 / 2} \mu_{\psi}(\Omega)^{1 / 2} \leq$
$\mu_{\varphi}(\mathbb{R})^{1 / 2} \mu_{\psi}(\mathbb{R})^{1 / 2} \leq\|\varphi\|\|\psi\|$. Hence Corollary 1.9 implies that there is indeed a family of nonnegative $\left(0 \leq\left\langle\psi, P_{A}(\Omega) \psi\right\rangle \leq 1\right)$ and hence self-adjoint operators $P_{A}(\Omega)$ such that

$$
\begin{equation*}
\left\langle\varphi, P_{A}(\Omega) \psi\right\rangle=\int_{\mathbb{R}} \chi_{\Omega}(\lambda) d \mu_{\varphi, \psi}(\lambda) . \tag{3.48}
\end{equation*}
$$

Lemma 3.6. The family of operators $P_{A}(\Omega)$ forms a projection-valued measure.

Proof. We first show $P_{A}\left(\Omega_{1}\right) P_{A}\left(\Omega_{2}\right)=P_{A}\left(\Omega_{1} \cap \Omega_{2}\right)$ in two steps. First observe (using the first resolvent formula (2.81))

$$
\begin{aligned}
& \int_{\mathbb{R}} \frac{1}{\lambda-\tilde{z}} d \mu_{R_{A}\left(z^{*}\right) \varphi, \psi}(\lambda)=\left\langle R_{A}\left(z^{*}\right) \varphi, R_{A}(\tilde{z}) \psi\right\rangle=\left\langle\varphi, R_{A}(z) R_{A}(\tilde{z}) \psi\right\rangle \\
&=\frac{1}{z-\tilde{z}}\left(\left\langle\varphi, R_{A}(z) \psi\right\rangle-\left\langle\varphi, R_{A}(\tilde{z}) \psi\right\rangle\right) \\
& \quad=\frac{1}{z-\tilde{z}} \int_{\mathbb{R}}\left(\frac{1}{\lambda-z}-\frac{1}{\lambda-\tilde{z}}\right) d \mu_{\varphi, \psi}(\lambda)=\int_{\mathbb{R}} \frac{1}{\lambda-\tilde{z}} \frac{d \mu_{\varphi, \psi}(\lambda)}{\lambda-z}
\end{aligned}
$$

implying $d \mu_{R_{A}\left(z^{*}\right) \varphi, \psi}(\lambda)=(\lambda-z)^{-1} d \mu_{\varphi, \psi}(\lambda)$ by Problem 3.21. Secondly we compute

$$
\begin{gathered}
\int_{\mathbb{R}} \frac{1}{\lambda-z} d \mu_{\varphi, P_{A}(\Omega) \psi}(\lambda)=\left\langle\varphi, R_{A}(z) P_{A}(\Omega) \psi\right\rangle=\left\langle R_{A}\left(z^{*}\right) \varphi, P_{A}(\Omega) \psi\right\rangle \\
=\int_{\mathbb{R}} \chi_{\Omega}(\lambda) d \mu_{R_{A}\left(z^{*}\right) \varphi, \psi}(\lambda)=\int_{\mathbb{R}} \frac{1}{\lambda-z} \chi_{\Omega}(\lambda) d \mu_{\varphi, \psi}(\lambda)
\end{gathered}
$$

implying $d \mu_{\varphi, P_{A}(\Omega) \psi}(\lambda)=\chi_{\Omega}(\lambda) d \mu_{\varphi, \psi}(\lambda)$. Equivalently we have

$$
\left\langle\varphi, P_{A}\left(\Omega_{1}\right) P_{A}\left(\Omega_{2}\right) \psi\right\rangle=\left\langle\varphi, P_{A}\left(\Omega_{1} \cap \Omega_{2}\right) \psi\right\rangle
$$

since $\chi_{\Omega_{1}} \chi_{\Omega_{2}}=\chi_{\Omega_{1} \cap \Omega_{2}}$. In particular, choosing $\Omega_{1}=\Omega_{2}$, we see that $P_{A}\left(\Omega_{1}\right)$ is a projector.

To see $P_{A}(\mathbb{R})=\mathbb{I}$, let $\psi \in \operatorname{Ker}\left(P_{A}(\mathbb{R})\right)$. Then $0=\left\langle\psi, P_{A}(\mathbb{R}) \psi\right\rangle=\mu_{\psi}(\mathbb{R})$ implies $\left\langle\psi, R_{A}(z) \psi\right\rangle=0$ which implies $\psi=0$.

Now let $\Omega=\bigcup_{n=1}^{\infty} \Omega_{n}$ with $\Omega_{n} \cap \Omega_{m}=\emptyset$ for $n \neq m$. Then

$$
\sum_{j=1}^{n}\left\langle\psi, P_{A}\left(\Omega_{j}\right) \psi\right\rangle=\sum_{j=1}^{n} \mu_{\psi}\left(\Omega_{j}\right) \rightarrow\left\langle\psi, P_{A}(\Omega) \psi\right\rangle=\mu_{\psi}(\Omega)
$$

by $\sigma$-additivity of $\mu_{\psi}$. Hence $P_{A}$ is weakly $\sigma$-additive which implies strong $\sigma$-additivity, as pointed out earlier.

Now we can prove the spectral theorem for self-adjoint operators.

Theorem 3.7 (Spectral theorem). To every self-adjoint operator $A$ there corresponds a unique projection-valued measure $P_{A}$ such that

$$
\begin{equation*}
A=\int_{\mathbb{R}} \lambda d P_{A}(\lambda) \tag{3.49}
\end{equation*}
$$

Proof. Existence has already been established. Moreover, Lemma 3.5 shows that $P_{A}\left((\lambda-z)^{-1}\right)=R_{A}(z), z \in \mathbb{C} \backslash \mathbb{R}$. Since the measures $\mu_{\varphi, \psi}$ are uniquely determined by the resolvent and the projection-valued measure is uniquely determined by the measures $\mu_{\varphi, \psi}$, we are done.

The quadratic form of $A$ is given by

$$
\begin{equation*}
q_{A}(\psi)=\int_{\mathbb{R}} \lambda d \mu_{\psi}(\lambda) \tag{3.50}
\end{equation*}
$$

and can be defined for every $\psi$ in the form domain

$$
\begin{equation*}
\mathfrak{Q}(A)=\mathfrak{D}\left(|A|^{1 / 2}\right)=\left\{\psi \in \mathfrak{H}\left|\int_{\mathbb{R}}\right| \lambda \mid d \mu_{\psi}(\lambda)<\infty\right\} \tag{3.51}
\end{equation*}
$$

(which is larger than the domain $\mathfrak{D}(A)=\left\{\psi \in \mathfrak{H} \mid \int_{\mathbb{R}} \lambda^{2} d \mu_{\psi}(\lambda)<\infty\right\}$ ). This extends our previous definition for nonnegative operators.

Note that if $A$ and $\tilde{A}$ are unitarily equivalent as in (3.30), then $U R_{A}(z)=$ $R_{\tilde{A}}(z) U$ and hence

$$
\begin{equation*}
d \mu_{\psi}=d \tilde{\mu}_{U \psi} . \tag{3.52}
\end{equation*}
$$

In particular, we have $U P_{A}(f)=P_{\tilde{A}}(f) U, U \mathfrak{D}\left(P_{A}(f)\right)=\mathfrak{D}\left(P_{\tilde{A}}(f)\right)$.
Finally, let us give a characterization of the spectrum of $A$ in terms of the associated projectors.

Theorem 3.8. The spectrum of $A$ is given by

$$
\begin{equation*}
\sigma(A)=\left\{\lambda \in \mathbb{R} \mid P_{A}((\lambda-\varepsilon, \lambda+\varepsilon)) \neq 0 \text { for all } \varepsilon>0\right\} . \tag{3.53}
\end{equation*}
$$

Proof. Let $\Omega_{n}=\left(\lambda_{0}-\frac{1}{n}, \lambda_{0}+\frac{1}{n}\right)$. Suppose $P_{A}\left(\Omega_{n}\right) \neq 0$. Then we can find a $\psi_{n} \in P_{A}\left(\Omega_{n}\right) \mathfrak{H}$ with $\left\|\psi_{n}\right\|=1$. Since

$$
\begin{aligned}
\left\|\left(A-\lambda_{0}\right) \psi_{n}\right\|^{2} & =\left\|\left(A-\lambda_{0}\right) P_{A}\left(\Omega_{n}\right) \psi_{n}\right\|^{2} \\
& =\int_{\mathbb{R}}\left(\lambda-\lambda_{0}\right)^{2} \chi_{\Omega_{n}}(\lambda) d \mu_{\psi_{n}}(\lambda) \leq \frac{1}{n^{2}}
\end{aligned}
$$

we conclude $\lambda_{0} \in \sigma(A)$ by Lemma 2.16.
Conversely, if $P_{A}\left(\left(\lambda_{0}-\varepsilon, \lambda_{0}+\varepsilon\right)\right)=0$, set

$$
f_{\varepsilon}(\lambda)=\chi_{\mathbb{R} \backslash\left(\lambda_{0}-\varepsilon, \lambda_{0}+\varepsilon\right)}(\lambda)\left(\lambda-\lambda_{0}\right)^{-1} .
$$

Then

$$
\left(A-\lambda_{0}\right) P_{A}\left(f_{\varepsilon}\right)=P_{A}\left(\left(\lambda-\lambda_{0}\right) f_{\varepsilon}(\lambda)\right)=P_{A}\left(\mathbb{R} \backslash\left(\lambda_{0}-\varepsilon, \lambda_{0}+\varepsilon\right)\right)=\mathbb{I} .
$$

Similarly $P_{A}\left(f_{\varepsilon}\right)\left(A-\lambda_{0}\right)=\left.\mathbb{I}\right|_{\mathfrak{D}(A)}$ and hence $\lambda_{0} \in \rho(A)$.

In particular, $P_{A}\left(\left(\lambda_{1}, \lambda_{2}\right)\right)=0$ if and only if $\left(\lambda_{1}, \lambda_{2}\right) \subseteq \rho(A)$.
Corollary 3.9. We have

$$
\begin{equation*}
P_{A}(\sigma(A))=\mathbb{I} \quad \text { and } \quad P_{A}(\mathbb{R} \cap \rho(A))=0 . \tag{3.54}
\end{equation*}
$$

Proof. For every $\lambda \in \mathbb{R} \cap \rho(A)$ there is some open interval $I_{\lambda}$ with $P_{A}\left(I_{\lambda}\right)=$ 0 . These intervals form an open cover for $\mathbb{R} \cap \rho(A)$ and there is a countable subcover $J_{n}$. Setting $\Omega_{n}=J_{n} \backslash \bigcup_{m<n} J_{m}$, we have disjoint Borel sets which cover $\mathbb{R} \cap \rho(A)$ and satisfy $P_{A}\left(\Omega_{n}\right)=0$. Finally, strong $\sigma$-additivity shows $P_{A}(\mathbb{R} \cap \rho(A)) \psi=\sum_{n} P_{A}\left(\Omega_{n}\right) \psi=0$.

Consequently,

$$
\begin{equation*}
P_{A}(f)=P_{A}(\sigma(A)) P_{A}(f)=P_{A}\left(\chi_{\sigma(A)} f\right) . \tag{3.55}
\end{equation*}
$$

In other words, $P_{A}(f)$ is not affected by the values of $f$ on $\mathbb{R} \backslash \sigma(A)$ !
It is clearly more intuitive to write $P_{A}(f)=f(A)$ and we will do so from now on. This notation is justified by the elementary observation

$$
\begin{equation*}
P_{A}\left(\sum_{j=0}^{n} \alpha_{j} \lambda^{j}\right)=\sum_{j=0}^{n} \alpha_{j} A^{j} . \tag{3.56}
\end{equation*}
$$

Moreover, this also shows that if $A$ is bounded and $f(A)$ can be defined via a convergent power series, then this agrees with our present definition by Theorem 3.1.

Problem 3.1. Show that a self-adjoint operator $P$ is a projection if and only if $\sigma(P) \subseteq\{0,1\}$.

Problem 3.2. Consider the parity operator $\Pi: L^{2}\left(\mathbb{R}^{n}\right) \rightarrow L^{2}\left(\mathbb{R}^{n}\right)$, $\psi(x) \mapsto \psi(-x)$. Show that $\Pi$ is self-adjoint. Compute its spectrum $\sigma(\Pi)$ and the corresponding projection-valued measure $P_{\Pi}$.

Problem 3.3. Show that (3.7) is a projection-valued measure. What is the corresponding operator?

Problem 3.4. Show that $P(\lambda)$ defined in (3.14) satisfies properties (i)-(iv) stated there.

Problem 3.5. Show that for a self-adjoint operator $A$ we have $\left\|R_{A}(z)\right\|=$ $\operatorname{dist}(z, \sigma(A))$.

Problem 3.6. Suppose $A$ is self-adjoint and $\left\|B-z_{0}\right\| \leq r$. Show that $\sigma(A+B) \subseteq \sigma(A)+\overline{B_{r}\left(z_{0}\right)}$, where $B_{r}\left(z_{0}\right)$ is the ball of radius $r$ around $z_{0}$. (Hint: Problem 2.17.)

Problem 3.7. Show that for a self-adjoint operator $A$ we have $\left\|A R_{A}(z)\right\| \leq$ $\frac{|z|}{\operatorname{Im}(z)}$. Find some A for which equality is attained.

Conclude that for every $\psi \in \mathfrak{H}$ we have

$$
\begin{equation*}
\lim _{z \rightarrow \infty}\left\|A R_{A}(z) \psi\right\|=0 \tag{3.57}
\end{equation*}
$$

where the limit is taken in any sector $\varepsilon|\operatorname{Re}(z)| \leq|\operatorname{Im}(z)|, \varepsilon>0$.
Problem 3.8. Suppose $A$ is self-adjoint. Show that, if $\psi \in \mathfrak{D}\left(A^{n}\right)$, then

$$
\begin{equation*}
R_{A}(z) \psi=-\sum_{j=0}^{n} \frac{A^{j} \psi}{z^{j+1}}+O\left(\frac{\left\|A^{n} \psi\right\|}{|z|^{n} \operatorname{Im}(z)}\right), \quad \text { as } \quad z \rightarrow \infty \tag{3.58}
\end{equation*}
$$

(Hint: Proceed as in (2.87) and use the previous problem.)
Problem 3.9. Let $\lambda_{0}$ be an eigenvalue and $\psi$ a corresponding normalized eigenvector. Compute $\mu_{\psi}$.
Problem 3.10. Show that $\lambda_{0}$ is an eigenvalue if and only if $P\left(\left\{\lambda_{0}\right\}\right) \neq 0$. Show that $\operatorname{Ran}\left(P\left(\left\{\lambda_{0}\right\}\right)\right)$ is the corresponding eigenspace in this case.

Problem 3.11 (Polar decomposition). Let $A$ be a closed operator and set $|A|=\sqrt{A^{*} A}$ (recall that, by Problem 2.12, $A^{*} A$ is self-adjoint and $\left.\mathfrak{Q}\left(A^{*} A\right)=\mathfrak{D}(A)\right)$. Show that

$$
\||A| \psi\|=\|A \psi\| .
$$

Conclude that $\operatorname{Ker}(A)=\operatorname{Ker}(|A|)=\operatorname{Ran}(|A|)^{\perp}$ and that

$$
U= \begin{cases}\varphi=|A| \psi \mapsto A \psi & \text { if } \varphi \in \operatorname{Ran}(|A|), \\ \varphi \mapsto 0 & \text { if } \varphi \in \operatorname{Ker}(|A|)\end{cases}
$$

extends to a well-defined partial isometry; that is, $U: \operatorname{Ker}(U)^{\perp} \rightarrow \operatorname{Ran}(U)$ is unitary, where $\operatorname{Ker}(U)=\operatorname{Ker}(A)$ and $\operatorname{Ran}(U)=\operatorname{Ker}\left(A^{*}\right)^{\perp}$.

In particular, we have the polar decomposition

$$
A=U|A| .
$$

Problem 3.12. Compute $|A|=\sqrt{A^{*} A}$ for the rank one operator $A=$ $\langle\varphi,.\rangle \psi$. Compute $\sqrt{A A^{*}}$ also.

### 3.2. More on Borel measures

Section 3.1 showed that in order to understand self-adjoint operators, one needs to understand multiplication operators on $L^{2}(\mathbb{R}, d \mu)$, where $d \mu$ is a finite Borel measure. This is the purpose of the present section.

The set of all growth points, that is,

$$
\begin{equation*}
\sigma(\mu)=\{\lambda \in \mathbb{R} \mid \mu((\lambda-\varepsilon, \lambda+\varepsilon))>0 \text { for all } \varepsilon>0\} \tag{3.59}
\end{equation*}
$$

is called the spectrum of $\mu$. The same proof as for Corollary 3.9 shows that the spectrum $\sigma=\sigma(\mu)$ is a support for $\mu$; that is, $\mu(\mathbb{R} \backslash \sigma)=0$.

In the previous section we have already seen that the Borel transform of $\mu$,

$$
\begin{equation*}
F(z)=\int_{\mathbb{R}} \frac{1}{\lambda-z} d \mu(\lambda) \tag{3.60}
\end{equation*}
$$

plays an important role.
Theorem 3.10. The Borel transform of a finite Borel measure is a Herglotz function. It is holomorphic in $\mathbb{C} \backslash \sigma(\mu)$ and satisfies

$$
\begin{equation*}
F\left(z^{*}\right)=F(z)^{*}, \quad|F(z)| \leq \frac{\mu(\mathbb{R})}{\operatorname{Im}(z)}, \quad z \in \mathbb{C}_{+} \tag{3.61}
\end{equation*}
$$

Proof. First of all note

$$
\operatorname{Im}(F(z))=\int_{\mathbb{R}} \operatorname{Im}\left(\frac{1}{\lambda-z}\right) d \mu(\lambda)=\operatorname{Im}(z) \int_{\mathbb{R}} \frac{d \mu(\lambda)}{|\lambda-z|^{2}}
$$

which shows that $F$ maps $\mathbb{C}_{+}$to $\mathbb{C}_{+}$. Moreover, $F\left(z^{*}\right)=F(z)^{*}$ is obvious and

$$
|F(z)| \leq \int_{\mathbb{R}} \frac{d \mu(\lambda)}{|\lambda-z|} \leq \frac{1}{\operatorname{Im}(z)} \int_{\mathbb{R}} d \mu(\lambda)
$$

establishes the bound. Moreover, since $\mu(\mathbb{R} \backslash \sigma)=0$, we have

$$
F(z)=\int_{\sigma} \frac{1}{\lambda-z} d \mu(\lambda)
$$

which together with the bound

$$
\frac{1}{|\lambda-z|} \leq \frac{1}{\operatorname{dist}(z, \sigma)}
$$

allows the application of the dominated convergence theorem to conclude that $F$ is continuous on $\mathbb{C} \backslash \sigma$. To show that $F$ is holomorphic in $\mathbb{C} \backslash \sigma$, by Morera's theorem, it suffices to check $\int_{\Gamma} F(z) d z=0$ for every triangle $\Gamma \subset \mathbb{C} \backslash \sigma$. Since $(\lambda-z)^{-1}$ is bounded for $(\lambda, z) \in \sigma \times \Gamma$, this follows from $\int_{\Gamma}(\lambda-z)^{-1} d z=0$ by using Fubini, $\int_{\Gamma} F(z) d z=\int_{\Gamma} \int_{\mathbb{R}}(\lambda-z)^{-1} d \mu(\lambda) d z=$ $\int_{\mathbb{R}} \int_{\Gamma}(\lambda-z)^{-1} d z d \mu(\lambda)=0$.

Note that $F$ cannot be holomorphically extended to a larger domain. In fact, if $F$ is holomorphic in a neighborhood of some $\lambda \in \mathbb{R}$, then $F(\lambda)=$ $F\left(\lambda^{*}\right)=F(\lambda)^{*}$ implies $\operatorname{Im}(F(\lambda))=0$ and the Stieltjes inversion formula (Theorem 3.21) shows that $\lambda \in \mathbb{R} \backslash \sigma(\mu)$.

Associated with this measure is the operator

$$
\begin{equation*}
A f(\lambda)=\lambda f(\lambda), \quad \mathfrak{D}(A)=\left\{f \in L^{2}(\mathbb{R}, d \mu) \mid \lambda f(\lambda) \in L^{2}(\mathbb{R}, d \mu)\right\} \tag{3.62}
\end{equation*}
$$

By Theorem 3.8 the spectrum of $A$ is precisely the spectrum of $\mu$; that is,

$$
\begin{equation*}
\sigma(A)=\sigma(\mu) . \tag{3.63}
\end{equation*}
$$

Note that $1 \in L^{2}(\mathbb{R}, d \mu)$ is a cyclic vector for $A$ and that

$$
\begin{equation*}
d \mu_{g, f}(\lambda)=g(\lambda)^{*} f(\lambda) d \mu(\lambda) \tag{3.64}
\end{equation*}
$$

Now what can we say about the function $f(A)$ (which is precisely the multiplication operator by $f$ ) of $A$ ? We are only interested in the case where $f$ is real-valued. Introduce the measure

$$
\begin{equation*}
\left(f_{\star} \mu\right)(\Omega)=\mu\left(f^{-1}(\Omega)\right) \tag{3.65}
\end{equation*}
$$

Then

$$
\begin{equation*}
\int_{\mathbb{R}} g(\lambda) d\left(f_{\star} \mu\right)(\lambda)=\int_{\mathbb{R}} g(f(\lambda)) d \mu(\lambda) . \tag{3.66}
\end{equation*}
$$

In fact, it suffices to check this formula for simple functions $g$, which follows since $\chi_{\Omega} \circ f=\chi_{f^{-1}(\Omega)}$. In particular, we have

$$
\begin{equation*}
P_{f(A)}(\Omega)=\chi_{f^{-1}(\Omega)} \tag{3.67}
\end{equation*}
$$

It is tempting to conjecture that $f(A)$ is unitarily equivalent to multiplication by $\lambda$ in $L^{2}\left(\mathbb{R}, d\left(f_{\star} \mu\right)\right)$ via the map

$$
\begin{equation*}
L^{2}\left(\mathbb{R}, d\left(f_{\star} \mu\right)\right) \rightarrow L^{2}(\mathbb{R}, d \mu), \quad g \mapsto g \circ f \tag{3.68}
\end{equation*}
$$

However, this map is only unitary if its range is $L^{2}(\mathbb{R}, d \mu)$.
Lemma 3.11. Suppose $f$ is injective. Then

$$
\begin{equation*}
U: L^{2}(\mathbb{R}, d \mu) \rightarrow L^{2}\left(\mathbb{R}, d\left(f_{\star} \mu\right)\right), \quad g \mapsto g \circ f^{-1} \tag{3.69}
\end{equation*}
$$

is a unitary map such that $U f(\lambda)=\lambda$.
Example. Let $f(\lambda)=\lambda^{2}$. Then $(g \circ f)(\lambda)=g\left(\lambda^{2}\right)$ and the range of the above map is given by the symmetric functions. Note that we can still get a unitary map $L^{2}\left(\mathbb{R}, d\left(f_{\star} \mu\right)\right) \oplus L^{2}\left(\mathbb{R}, d\left(f_{\star} \mu\right)\right) \rightarrow L^{2}(\mathbb{R}, d \mu),\left(g_{1}, g_{2}\right) \mapsto$ $g_{1}\left(\lambda^{2}\right)+g_{2}\left(\lambda^{2}\right)\left(\chi_{(0, \infty)}(\lambda)-\chi_{(0, \infty)}(-\lambda)\right)$.

Lemma 3.12. Let $f$ be real-valued. The spectrum of $f(A)$ is given by

$$
\begin{equation*}
\sigma(f(A))=\sigma\left(f_{\star} \mu\right) . \tag{3.70}
\end{equation*}
$$

In particular,

$$
\begin{equation*}
\sigma(f(A)) \subseteq \overline{f(\sigma(A))} \tag{3.71}
\end{equation*}
$$

where equality holds if $f$ is continuous and the closure can be dropped if, in addition, $\sigma(A)$ is bounded (i.e., compact).

Proof. The first formula follows by comparing

$$
\sigma\left(f_{\star} \mu\right)=\left\{\lambda \in \mathbb{R} \mid \mu\left(f^{-1}(\lambda-\varepsilon, \lambda+\varepsilon)\right)>0 \text { for all } \varepsilon>0\right\}
$$

with (2.74).

If $f$ is continuous, $f^{-1}((f(\lambda)-\varepsilon, f(\lambda)+\varepsilon))$ contains an open interval around $\lambda$ and hence $f(\lambda) \in \sigma(f(A))$ if $\lambda \in \sigma(A)$. If, in addition, $\sigma(A)$ is compact, then $f(\sigma(A))$ is compact and hence closed.

Whether two operators with simple spectrum are unitarily equivalent can be read off from the corresponding measures:

Lemma 3.13. Let $A_{1}, A_{2}$ be self-adjoint operators with simple spectrum and corresponding spectral measures $\mu_{1}$ and $\mu_{2}$ of cyclic vectors. Then $A_{1}$ and $A_{2}$ are unitarily equivalent if and only if $\mu_{1}$ and $\mu_{2}$ are mutually absolutely continuous.

Proof. Without restriction we can assume that $A_{j}$ is multiplication by $\lambda$ in $L^{2}\left(\mathbb{R}, d \mu_{j}\right)$. Let $U: L^{2}\left(\mathbb{R}, d \mu_{1}\right) \rightarrow L^{2}\left(\mathbb{R}, d \mu_{2}\right)$ be a unitary map such that $U A_{1}=A_{2} U$. Then we also have $U f\left(A_{1}\right)=f\left(A_{2}\right) U$ for any bounded Borel function and hence

$$
U f(\lambda)=U f(\lambda) \cdot 1=f(\lambda) U(1)(\lambda)
$$

and thus $U$ is multiplication by $u(\lambda)=U(1)(\lambda)$. Moreover, since $U$ is unitary, we have

$$
\mu_{1}(\Omega)=\int_{\mathbb{R}}\left|\chi_{\Omega}\right|^{2} d \mu_{1}=\int_{\mathbb{R}}\left|u \chi_{\Omega}\right|^{2} d \mu_{2}=\int_{\Omega}|u|^{2} d \mu_{2}
$$

that is, $d \mu_{1}=|u|^{2} d \mu_{2}$. Reversing the roles of $A_{1}$ and $A_{2}$, we obtain $d \mu_{2}=$ $|v|^{2} d \mu_{1}$, where $v=U^{-1} 1$.

The converse is left as an exercise (Problem 3.17).
Next we recall the unique decomposition of $\mu$ with respect to Lebesgue measure,

$$
\begin{equation*}
d \mu=d \mu_{a c}+d \mu_{s} \tag{3.72}
\end{equation*}
$$

where $\mu_{a c}$ is absolutely continuous with respect to Lebesgue measure (i.e., we have $\mu_{a c}(B)=0$ for all $B$ with Lebesgue measure zero) and $\mu_{s}$ is singular with respect to Lebesgue measure (i.e., $\mu_{s}$ is supported, $\mu_{s}(\mathbb{R} \backslash B)=0$, on a set $B$ with Lebesgue measure zero). The singular part $\mu_{s}$ can be further decomposed into a (singularly) continuous and a pure point part,

$$
\begin{equation*}
d \mu_{s}=d \mu_{s c}+d \mu_{p p}, \tag{3.73}
\end{equation*}
$$

where $\mu_{s c}$ is continuous on $\mathbb{R}$ and $\mu_{p p}$ is a step function. Since the measures $d \mu_{a c}, d \mu_{s c}$, and $d \mu_{p p}$ are mutually singular, they have mutually disjoint supports $M_{a c}, M_{s c}$, and $M_{p p}$. Note that these sets are not unique. We will choose them such that $M_{p p}$ is the set of all jumps of $\mu(\lambda)$ and such that $M_{s c}$ has Lebesgue measure zero.

To the sets $M_{a c}, M_{s c}$, and $M_{p p}$ correspond projectors $P^{a c}=\chi_{M_{a c}}(A)$, $P^{s c}=\chi_{M_{s c}}(A)$, and $P^{p p}=\chi_{M_{p p}}(A)$ satisfying $P^{a c}+P^{s c}+P^{p p}=\mathbb{I}$. In
other words, we have a corresponding direct sum decomposition of both our Hilbert space

$$
\begin{equation*}
L^{2}(\mathbb{R}, d \mu)=L^{2}\left(\mathbb{R}, d \mu_{a c}\right) \oplus L^{2}\left(\mathbb{R}, d \mu_{s c}\right) \oplus L^{2}\left(\mathbb{R}, d \mu_{p p}\right) \tag{3.74}
\end{equation*}
$$

and our operator

$$
\begin{equation*}
A=\left(A P^{a c}\right) \oplus\left(A P^{s c}\right) \oplus\left(A P^{p p}\right) \tag{3.75}
\end{equation*}
$$

The corresponding spectra, $\sigma_{a c}(A)=\sigma\left(\mu_{a c}\right), \sigma_{s c}(A)=\sigma\left(\mu_{s c}\right)$, and $\sigma_{p p}(A)=$ $\sigma\left(\mu_{p p}\right)$ are called the absolutely continuous, singularly continuous, and pure point spectrum of $A$, respectively.

It is important to observe that $\sigma_{p p}(A)$ is in general not equal to the set of eigenvalues

$$
\begin{equation*}
\sigma_{p}(A)=\{\lambda \in \mathbb{R} \mid \lambda \text { is an eigenvalue of } A\} \tag{3.76}
\end{equation*}
$$

since we only have $\sigma_{p p}(A)=\overline{\sigma_{p}(A)}$.
Example. Let $\mathfrak{H}=\ell^{2}(\mathbb{N})$ and let $A$ be given by $A \delta_{n}=\frac{1}{n} \delta_{n}$, where $\delta_{n}$ is the sequence which is 1 at the $n$ 'th place and zero otherwise (that is, $A$ is a diagonal matrix with diagonal elements $\frac{1}{n}$ ). Then $\sigma_{p}(A)=\left\{\left.\frac{1}{n} \right\rvert\, n \in \mathbb{N}\right\}$ but $\sigma(A)=\sigma_{p p}(A)=\sigma_{p}(A) \cup\{0\}$. To see this, just observe that $\delta_{n}$ is the eigenvector corresponding to the eigenvalue $\frac{1}{n}$ and for $z \notin \sigma(A)$ we have $R_{A}(z) \delta_{n}=\frac{n}{1-n z} \delta_{n}$. At $z=0$ this formula still gives the inverse of $A$, but it is unbounded and hence $0 \in \sigma(A)$ but $0 \notin \sigma_{p}(A)$. Since a continuous measure cannot live on a single point and hence also not on a countable set, we have $\sigma_{a c}(A)=\sigma_{s c}(A)=\emptyset$.

Example. An example with purely absolutely continuous spectrum is given by taking $\mu$ to be the Lebesgue measure. An example with purely singularly continuous spectrum is given by taking $\mu$ to be the Cantor measure.

Finally, we show how the spectrum can be read off from the boundary values of $\operatorname{Im}(F)$ towards the real line. We define the following sets:

$$
\begin{align*}
M_{a c} & =\{\lambda \mid 0<\underset{\varepsilon \downarrow 0}{\lim \sup } \operatorname{Im}(F(\lambda+\mathrm{i} \varepsilon))<\infty\} \\
M_{s} & =\{\lambda \mid \underset{\varepsilon \downarrow 0}{\lim \sup } \operatorname{Im}(F(\lambda+\mathrm{i} \varepsilon))=\infty\}  \tag{3.77}\\
M & =M_{a c} \cup M_{s}=\{\lambda \mid 0<\underset{\varepsilon \downarrow 0}{\lim \sup } \operatorname{Im}(F(\lambda+\mathrm{i} \varepsilon))\} .
\end{align*}
$$

Then, by Theorem 3.23 we conclude that these sets are minimal supports for $\mu_{a c}, \mu_{s}$, and $\mu$, respectively. In fact, by Theorem 3.23 we could even restrict ourselves to values of $\lambda$, where the limsup is a lim (finite or infinite).
Lemma 3.14. The spectrum of $\mu$ is given by

$$
\begin{equation*}
\sigma(\mu)=\bar{M}, \quad M=\left\{\lambda \mid 0<\liminf _{\varepsilon \downarrow 0} \operatorname{Im}(F(\lambda+\mathrm{i} \varepsilon))\right\} . \tag{3.78}
\end{equation*}
$$

Proof. First observe that $F$ is real holomorphic near $\lambda \notin \sigma(\mu)$ and hence $\operatorname{Im}(F(\lambda))=0$ in this case. Thus $M \subseteq \sigma(\mu)$ and since $\sigma(\mu)$ is closed, we even have $\bar{M} \subseteq \sigma(\mu)$. To see the converse, note that by Theorem 3.23, the set $M$ is a support for $M$. Thus, if $\lambda \in \sigma(\mu)$, then

$$
0<\mu((\lambda-\varepsilon, \lambda+\varepsilon))=\mu((\lambda-\varepsilon, \lambda+\varepsilon) \cap M)
$$

for all $\varepsilon>0$ and we can find a sequence $\lambda_{n} \in(\lambda-1 / n, \lambda+1 / n) \cap M$ converging to $\lambda$ from inside $M$. This shows the remaining part $\sigma(\mu) \subseteq \bar{M}$.

To recover $\sigma\left(\mu_{a c}\right)$ from $M_{a c}$, we need the essential closure of a Borel set $N \subseteq \mathbb{R}$,

$$
\begin{equation*}
\bar{N}^{\text {ess }}=\{\lambda \in \mathbb{R} \|(\lambda-\varepsilon, \lambda+\varepsilon) \cap N \mid>0 \text { for all } \varepsilon>0\} . \tag{3.79}
\end{equation*}
$$

Note that $\bar{N}^{\text {ess }}$ is closed, whereas, in contradistinction to the ordinary closure, we might have $N \not \subset \bar{N} \bar{N}^{e s s}$ (e.g., any isolated point of $N$ will disappear).

Lemma 3.15. The absolutely continuous spectrum of $\mu$ is given by

$$
\begin{equation*}
\sigma\left(\mu_{a c}\right)=\bar{M}_{a c}^{e s s} . \tag{3.80}
\end{equation*}
$$

Proof. We use that $0<\mu_{a c}((\lambda-\varepsilon, \lambda+\varepsilon))=\mu_{a c}\left((\lambda-\varepsilon, \lambda+\varepsilon) \cap M_{a c}\right)$ is equivalent to $\left|(\lambda-\varepsilon, \lambda+\varepsilon) \cap M_{a c}\right|>0$. One direction follows from the definition of absolute continuity and the other from minimality of $M_{a c}$.

Problem 3.13. Construct a multiplication operator on $L^{2}(\mathbb{R})$ which has dense point spectrum.

Problem 3.14. Let $\lambda$ be Lebesgue measure on $\mathbb{R}$. Show that if $f \in A C(\mathbb{R})$ with $f^{\prime}>0$, then

$$
d\left(f_{\star} \lambda\right)=\frac{1}{f^{\prime}(\lambda)} d \lambda
$$

Problem 3.15. Let $d \mu(\lambda)=\chi_{[0,1]}(\lambda) d \lambda$ and $f(\lambda)=\chi_{(-\infty, t]}(\lambda), t \in \mathbb{R}$. Compute $f_{\star} \mu$.

Problem 3.16. Let $A$ be the multiplication operator by the Cantor function in $L^{2}(0,1)$. Compute the spectrum of $A$. Determine the spectral types.

Problem 3.17. Show the missing direction in the proof of Lemma 3.13.
Problem 3.18. Show $\bar{N}^{e s s} \subseteq \bar{N}$.

### 3.3. Spectral types

Our next aim is to transfer the results of the previous section to arbitrary self-adjoint operators $A$ using Lemma 3.4. To this end, we will need a spectral measure which contains the information from all measures in a spectral basis. This will be the case if there is a vector $\psi$ such that for every
$\varphi \in \mathfrak{H}$ its spectral measure $\mu_{\varphi}$ is absolutely continuous with respect to $\mu_{\psi}$. Such a vector will be called a maximal spectral vector of $A$ and $\mu_{\psi}$ will be called a maximal spectral measure of $A$.

Lemma 3.16. For every self-adjoint operator $A$ there is a maximal spectral vector.

Proof. Let $\left\{\psi_{j}\right\}_{j \in J}$ be a spectral basis and choose nonzero numbers $\varepsilon_{j}$ with $\sum_{j \in J}\left|\varepsilon_{j}\right|^{2}=1$. Then I claim that

$$
\psi=\sum_{j \in J} \varepsilon_{j} \psi_{j}
$$

is a maximal spectral vector. Let $\varphi$ be given. Then we can write it as $\varphi=$ $\sum_{j} f_{j}(A) \psi_{j}$ and hence $d \mu_{\varphi}=\sum_{j}\left|f_{j}\right|^{2} d \mu_{\psi_{j}}$. But $\mu_{\psi}(\Omega)=\sum_{j}\left|\varepsilon_{j}\right|^{2} \mu_{\psi_{j}}(\Omega)=$ 0 implies $\mu_{\psi_{j}}(\Omega)=0$ for every $j \in J$ and thus $\mu_{\varphi}(\Omega)=0$.

A set $\left\{\psi_{j}\right\}$ of spectral vectors is called ordered if $\psi_{k}$ is a maximal spectral vector for $A$ restricted to $\left(\bigoplus_{j=1}^{k-1} \mathfrak{H}_{\psi_{j}}\right)^{\perp}$. As in the unordered case one can show

Theorem 3.17. For every self-adjoint operator there is an ordered spectral basis.

Observe that if $\left\{\psi_{j}\right\}$ is an ordered spectral basis, then $\mu_{\psi_{j+1}}$ is absolutely continuous with respect to $\mu_{\psi_{j}}$.

If $\mu$ is a maximal spectral measure, we have $\sigma(A)=\sigma(\mu)$ and the following generalization of Lemma 3.12 holds.

Theorem 3.18 (Spectral mapping). Let $\mu$ be a maximal spectral measure and let $f$ be real-valued. Then the spectrum of $f(A)$ is given by

$$
\begin{equation*}
\sigma(f(A))=\left\{\lambda \in \mathbb{R} \mid \mu\left(f^{-1}(\lambda-\varepsilon, \lambda+\varepsilon)\right)>0 \text { for all } \varepsilon>0\right\} . \tag{3.81}
\end{equation*}
$$

In particular,

$$
\begin{equation*}
\sigma(f(A)) \subseteq \overline{f(\sigma(A))} \tag{3.82}
\end{equation*}
$$

where equality holds if $f$ is continuous and the closure can be dropped if, in addition, $\sigma(A)$ is bounded.

Next, we want to introduce the splitting (3.74) for arbitrary self-adjoint operators $A$. It is tempting to pick a spectral basis and treat each summand in the direct sum separately. However, since it is not clear that this approach is independent of the spectral basis chosen, we use the more sophisticated
definition

$$
\begin{align*}
\mathfrak{H}_{a c} & =\left\{\psi \in \mathfrak{H} \mid \mu_{\psi} \text { is absolutely continuous }\right\}, \\
\mathfrak{H}_{s c} & =\left\{\psi \in \mathfrak{H} \mid \mu_{\psi} \text { is singularly continuous }\right\}, \\
\mathfrak{H}_{p p} & =\left\{\psi \in \mathfrak{H} \mid \mu_{\psi} \text { is pure point }\right\} . \tag{3.83}
\end{align*}
$$

Lemma 3.19. We have

$$
\begin{equation*}
\mathfrak{H}=\mathfrak{H}_{a c} \oplus \mathfrak{H}_{s c} \oplus \mathfrak{H}_{p p} . \tag{3.84}
\end{equation*}
$$

There are Borel sets $M_{x x}$ such that the projector onto $\mathfrak{H}_{x x}$ is given by $P^{x x}=$ $\chi_{M_{x x}}(A), x x \in\{a c, s c, p p\}$. In particular, the subspaces $\mathfrak{H}_{x x}$ reduce $A$. For the sets $M_{x x}$ one can choose the corresponding supports of some maximal spectral measure $\mu$.

Proof. We will use the unitary operator $U$ of Lemma 3.4. Pick $\varphi \in \mathfrak{H}$ and write $\varphi=\sum_{n} \varphi_{n}$ with $\varphi_{n} \in \mathfrak{H}_{\psi_{n}}$. Let $f_{n}=U \varphi_{n}$. Then, by construction of the unitary operator $U, \varphi_{n}=f_{n}(A) \psi_{n}$ and hence $d \mu_{\varphi_{n}}=\left|f_{n}\right|^{2} d \mu_{\psi_{n}}$. Moreover, since the subspaces $\mathfrak{H}_{\psi_{n}}$ are orthogonal, we have

$$
d \mu_{\varphi}=\sum_{n}\left|f_{n}\right|^{2} d \mu_{\psi_{n}}
$$

and hence

$$
d \mu_{\varphi, x x}=\sum_{n}\left|f_{n}\right|^{2} d \mu_{\psi_{n}, x x}, \quad x x \in\{a c, s c, p p\} .
$$

This shows

$$
U \mathfrak{H}_{x x}=\bigoplus_{n} L^{2}\left(\mathbb{R}, d \mu_{\psi_{n}, x x}\right), \quad x x \in\{a c, s c, p p\}
$$

and reduces our problem to the considerations of the previous section.
Furthermore, note that if $\mu$ is a maximal spectral measure, then every support for $\mu_{x x}$ is also a support for $\mu_{\varphi, x x}$ for any $\varphi \in \mathfrak{H}$.

The absolutely continuous, singularly continuous, and pure point spectrum of $A$ are defined as

$$
\begin{equation*}
\sigma_{a c}(A)=\sigma\left(\left.A\right|_{\mathfrak{H}_{a c}}\right), \quad \sigma_{s c}(A)=\sigma\left(\left.A\right|_{\mathfrak{H}_{s c}}\right), \quad \text { and } \quad \sigma_{p p}(A)=\sigma\left(\left.A\right|_{\mathfrak{S}_{p p}}\right), \tag{3.85}
\end{equation*}
$$

respectively. If $\mu$ is a maximal spectral measure, we have $\sigma_{a c}(A)=\sigma\left(\mu_{a c}\right)$, $\sigma_{s c}(A)=\sigma\left(\mu_{s c}\right)$, and $\sigma_{p p}(A)=\sigma\left(\mu_{p p}\right)$.

If $A$ and $\tilde{A}$ are unitarily equivalent via $U$, then so are $\left.A\right|_{\mathfrak{H}_{x x}}$ and $\left.\tilde{A}\right|_{\tilde{\mathfrak{H}}_{x x}}$ by (3.52). In particular, $\sigma_{x x}(A)=\sigma_{x x}(\tilde{A})$.
Problem 3.19. Compute $\sigma(A), \sigma_{a c}(A), \sigma_{s c}(A)$, and $\sigma_{p p}(A)$ for the multiplication operator $A=\frac{1}{1+x^{2}}$ in $L^{2}(\mathbb{R})$. What is its spectral multiplicity?

### 3.4. Appendix: The Herglotz theorem

Let $\mathbb{C}_{ \pm}=\{z \in \mathbb{C} \mid \pm \operatorname{Im}(z)>0\}$ be the upper, respectively, lower, half plane. A holomorphic function $F: \mathbb{C}_{+} \rightarrow \mathbb{C}_{+}$mapping the upper half plane to itself is called a Herglotz function. We can define $F$ on $\mathbb{C}_{\text {- }}$ using $F\left(z^{*}\right)=F(z)^{*}$.

In Theorem 3.10 we have seen that the Borel transform of a finite measure is a Herglotz function satisfying a growth estimate. It turns out that the converse is also true.

Theorem 3.20 (Herglotz representation). Suppose $F$ is a Herglotz function satisfying

$$
\begin{equation*}
|F(z)| \leq \frac{M}{\operatorname{Im}(z)}, \quad z \in \mathbb{C}_{+} \tag{3.86}
\end{equation*}
$$

Then there is a Borel measure $\mu$, satisfying $\mu(\mathbb{R}) \leq M$, such that $F$ is the Borel transform of $\mu$.

Proof. We abbreviate $F(z)=v(z)+\mathrm{i} w(z)$ and $z=x+\mathrm{i} y$. Next we choose a contour

$$
\Gamma=\{x+\mathrm{i} \varepsilon+\lambda \mid \lambda \in[-R, R]\} \cup\left\{x+\mathrm{i} \varepsilon+\operatorname{Re}^{\mathrm{i} \varphi} \mid \varphi \in[0, \pi]\right\}
$$

and note that $z$ lies inside $\Gamma$ and $z^{*}+2 \mathrm{i} \varepsilon$ lies outside $\Gamma$ if $0<\varepsilon<y<R$. Hence we have by Cauchy's formula

$$
F(z)=\frac{1}{2 \pi \mathrm{i}} \int_{\Gamma}\left(\frac{1}{\zeta-z}-\frac{1}{\zeta-z^{*}-2 \mathrm{i} \varepsilon}\right) F(\zeta) d \zeta .
$$

Inserting the explicit form of $\Gamma$, we see

$$
\begin{aligned}
F(z)= & \frac{1}{\pi} \int_{-R}^{R} \frac{y-\varepsilon}{\lambda^{2}+(y-\varepsilon)^{2}} F(x+\mathrm{i} \varepsilon+\lambda) d \lambda \\
& +\frac{\mathrm{i}}{\pi} \int_{0}^{\pi} \frac{y-\varepsilon}{R^{2} \mathrm{e}^{2 \mathrm{i} \varphi}+(y-\varepsilon)^{2}} F\left(x+\mathrm{i} \varepsilon+R \mathrm{e}^{\mathrm{i} \varphi}\right) R \mathrm{e}^{\mathrm{i} \varphi} d \varphi .
\end{aligned}
$$

The integral over the semi-circle vanishes as $R \rightarrow \infty$ and hence we obtain

$$
F(z)=\frac{1}{\pi} \int_{\mathbb{R}} \frac{y-\varepsilon}{(\lambda-x)^{2}+(y-\varepsilon)^{2}} F(\lambda+\mathrm{i} \varepsilon) d \lambda
$$

and taking imaginary parts,

$$
w(z)=\int_{\mathbb{R}} \phi_{\varepsilon}(\lambda) w_{\varepsilon}(\lambda) d \lambda
$$

where $\phi_{\varepsilon}(\lambda)=(y-\varepsilon) /\left((\lambda-x)^{2}+(y-\varepsilon)^{2}\right)$ and $w_{\varepsilon}(\lambda)=w(\lambda+\mathrm{i} \varepsilon) / \pi$. Letting $y \rightarrow \infty$, we infer from our bound

$$
\int_{\mathbb{R}} w_{\varepsilon}(\lambda) d \lambda \leq M
$$

In particular, since $\left|\phi_{\varepsilon}(\lambda)-\phi_{0}(\lambda)\right| \leq$ const $\varepsilon$, we have

$$
w(z)=\lim _{\varepsilon \downarrow 0} \int_{\mathbb{R}} \phi_{0}(\lambda) d \mu_{\varepsilon}(\lambda)
$$

where $\mu_{\varepsilon}(\lambda)=\int_{-\infty}^{\lambda} w_{\varepsilon}(x) d x$. Since $\mu_{\varepsilon}(\mathbb{R}) \leq M$, Lemma A. 26 implies that there is subsequence which converges vaguely to some measure $\mu$. Moreover, by Lemma A. 27 we even have

$$
w(z)=\int_{\mathbb{R}} \phi_{0}(\lambda) d \mu(\lambda) .
$$

Now $F(z)$ and $\int_{\mathbb{R}}(\lambda-z)^{-1} d \mu(\lambda)$ have the same imaginary part and thus they only differ by a real constant. By our bound this constant must be zero.

Observe

$$
\begin{equation*}
\operatorname{Im}(F(z))=\operatorname{Im}(z) \int_{\mathbb{R}} \frac{d \mu(\lambda)}{|\lambda-z|^{2}} \tag{3.87}
\end{equation*}
$$

and

$$
\begin{equation*}
\lim _{\lambda \rightarrow \infty} \lambda \operatorname{Im}(F(\mathrm{i} \lambda))=\mu(\mathbb{R}) . \tag{3.88}
\end{equation*}
$$

Theorem 3.21. Let $F$ be the Borel transform of some finite Borel measure $\mu$. Then the measure $\mu$ is unique and can be reconstructed via the Stieltjes inversion formula

$$
\begin{equation*}
\frac{1}{2}\left(\mu\left(\left(\lambda_{1}, \lambda_{2}\right)\right)+\mu\left(\left[\lambda_{1}, \lambda_{2}\right]\right)\right)=\lim _{\varepsilon \downarrow 0} \frac{1}{\pi} \int_{\lambda_{1}}^{\lambda_{2}} \operatorname{Im}(F(\lambda+\mathrm{i} \varepsilon)) d \lambda . \tag{3.89}
\end{equation*}
$$

Proof. By Fubini we have

$$
\begin{aligned}
\frac{1}{\pi} \int_{\lambda_{1}}^{\lambda_{2}} \operatorname{Im}(F(\lambda+\mathrm{i} \varepsilon)) d \lambda & =\frac{1}{\pi} \int_{\lambda_{1}}^{\lambda_{2}} \int_{\mathbb{R}} \frac{\varepsilon}{(x-\lambda)^{2}+\varepsilon^{2}} d \mu(x) d \lambda \\
& =\int_{\mathbb{R}} \frac{1}{\pi} \int_{\lambda_{1}}^{\lambda_{2}} \frac{\varepsilon}{(x-\lambda)^{2}+\varepsilon^{2}} d \lambda d \mu(x),
\end{aligned}
$$

where

$$
\begin{aligned}
\frac{1}{\pi} \int_{\lambda_{1}}^{\lambda_{2}} \frac{\varepsilon}{(x-\lambda)^{2}+\varepsilon^{2}} d \lambda & =\frac{1}{\pi}\left(\arctan \left(\frac{\lambda_{2}-x}{\varepsilon}\right)-\arctan \left(\frac{\lambda_{1}-x}{\varepsilon}\right)\right) \\
& \rightarrow \frac{1}{2}\left(\chi_{\left[\lambda_{1}, \lambda_{2}\right]}(x)+\chi_{\left(\lambda_{1}, \lambda_{2}\right)}(x)\right)
\end{aligned}
$$

pointwise. Hence the result follows from the dominated convergence theorem since $0 \leq \frac{1}{\pi}\left(\arctan \left(\frac{\lambda_{2}-x}{\varepsilon}\right)-\arctan \left(\frac{\lambda_{1}-x}{\varepsilon}\right)\right) \leq 1$.

Furthermore, the Radon-Nikodym derivative of $\mu$ can be obtained from the boundary values of $F$.

Theorem 3.22. Let $\mu$ be a finite Borel measure and $F$ its Borel transform. Then

$$
\begin{equation*}
(\underline{D} \mu)(\lambda) \leq \liminf _{\varepsilon \downarrow 0} \frac{1}{\pi} F(\lambda+\mathrm{i} \varepsilon) \leq \limsup _{\varepsilon \downarrow 0} \frac{1}{\pi} F(\lambda+\mathrm{i} \varepsilon) \leq(\bar{D} \mu)(\lambda) . \tag{3.90}
\end{equation*}
$$

Proof. We need to estimate

$$
\operatorname{Im}(F(\lambda+\mathrm{i} \varepsilon))=\int_{\mathbb{R}} K_{\varepsilon}(t) d \mu(t), \quad K_{\varepsilon}(t)=\frac{\varepsilon}{t^{2}+\varepsilon^{2}} .
$$

We first split the integral into two parts:
$\operatorname{Im}(F(\lambda+\mathrm{i} \varepsilon))=\int_{I_{\delta}} K_{\varepsilon}(t-\lambda) d \mu(t)+\int_{\mathbb{R} \backslash I_{\delta}} K_{\varepsilon}(t-\lambda) \mu(t), \quad I_{\delta}=(\lambda-\delta, \lambda+\delta)$.
Clearly the second part can be estimated by

$$
\int_{\mathbb{R} \backslash I_{\delta}} K_{\varepsilon}(t-\lambda) \mu(t) \leq K_{\varepsilon}(\delta) \mu(\mathbb{R}) .
$$

To estimate the first part, we integrate

$$
K_{\varepsilon}^{\prime}(s) d s d \mu(t)
$$

over the triangle $\{(s, t) \mid \lambda-s<t<\lambda+s, 0<s<\delta\}=\{(s, t) \mid \lambda-\delta<t<$ $\lambda+\delta, t-\lambda<s<\delta\}$ and obtain

$$
\int_{0}^{\delta} \mu\left(I_{s}\right) K_{\varepsilon}^{\prime}(s) d s=\int_{I_{\delta}}\left(K(\delta)-K_{\varepsilon}(t-\lambda)\right) d \mu(t)
$$

Now suppose there are constants $c$ and $C$ such that $c \leq \frac{\mu\left(I_{s}\right)}{2 s} \leq C, 0 \leq s \leq \delta$. Then

$$
2 c \arctan \left(\frac{\delta}{\varepsilon}\right) \leq \int_{I_{\delta}} K_{\varepsilon}(t-\lambda) d \mu(t) \leq 2 C \arctan \left(\frac{\delta}{\varepsilon}\right)
$$

since

$$
\delta K_{\varepsilon}(\delta)+\int_{0}^{\delta}-s K_{\varepsilon}^{\prime}(s) d s=\arctan \left(\frac{\delta}{\varepsilon}\right)
$$

Thus the claim follows combining both estimates.
As a consequence of Theorem A. 37 and Theorem A. 38 we obtain (cf. also Lemma A.39)
Theorem 3.23. Let $\mu$ be a finite Borel measure and $F$ its Borel transform. Then the limit

$$
\begin{equation*}
\operatorname{Im}(F(\lambda))=\lim _{\varepsilon \downarrow 0} \frac{1}{\pi} \operatorname{Im}(F(\lambda+\mathrm{i} \varepsilon)) \tag{3.91}
\end{equation*}
$$

exists a.e. with respect to both $\mu$ and Lebesgue measure (finite or infinite) and

$$
\begin{equation*}
(D \mu)(\lambda)=\frac{1}{\pi} \operatorname{Im}(F(\lambda)) \tag{3.92}
\end{equation*}
$$

whenever $(D \mu)(\lambda)$ exists.

Moreover, the set $\{\lambda \mid \operatorname{Im}(F(\lambda))=\infty\}$ is a support for the singularly continuous part and $\{\lambda \mid 0<\operatorname{Im}(F(\lambda))<\infty\}$ is a minimal support for the absolutely continuous part.

In particular,
Corollary 3.24. The measure $\mu$ is purely absolutely continuous on I if $\lim \sup _{\varepsilon \downarrow 0} \operatorname{Im}(F(\lambda+\mathrm{i} \varepsilon))<\infty$ for all $\lambda \in I$.

The limit of the real part can be computed as well.
Corollary 3.25. The limit

$$
\begin{equation*}
\lim _{\varepsilon \downarrow 0} F(\lambda+\mathrm{i} \varepsilon) \tag{3.93}
\end{equation*}
$$

exists a.e. with respect to both $\mu$ and Lebesgue measure. It is finite a.e. with respect to Lebesgue measure.

Proof. If $F(z)$ is a Herglotz function, then so is $\sqrt{F(z)}$. Moreover, $\sqrt{F(z)}$ has values in the first quadrant; that is, both $\operatorname{Re}(\sqrt{F(z)})$ and $\operatorname{Im}(\sqrt{F(z)})$ are positive for $z \in \mathbb{C}_{+}$. Hence both $\sqrt{F(z)}$ and $\mathrm{i} \sqrt{F(z)}$ are Herglotz functions and by Theorem 3.23 both $\lim _{\varepsilon \downarrow 0} \operatorname{Re}(\sqrt{F(\lambda+\mathrm{i} \varepsilon)})$ and $\lim _{\varepsilon \downarrow 0} \operatorname{Im}(\sqrt{F(\lambda+\mathrm{i} \varepsilon)})$ exist and are finite a.e. with respect to Lebesgue measure. By taking squares, the same is true for $F(z)$ and hence $\lim _{\varepsilon \downarrow 0} F(\lambda+\mathrm{i} \varepsilon)$ exists and is finite a.e. with respect to Lebesgue measure. Since $\lim _{\varepsilon \downarrow 0} \operatorname{Im}(F(\lambda+\mathrm{i} \varepsilon))=\infty$ implies $\lim _{\varepsilon \downarrow 0} F(\lambda+\mathrm{i} \varepsilon)=\infty$, the result follows.

Problem 3.20. Find all rational Herglotz functions $F: \mathbb{C} \rightarrow \mathbb{C}$ satisfying $F\left(z^{*}\right)=F(z)^{*}$ and $\lim _{|z| \rightarrow \infty}|z F(z)|=M<\infty$. What can you say about the zeros of $F$ ?

Problem 3.21. A complex measure $d \mu$ is a measure which can be written as a complex linear combinations of positive measures $d \mu_{j}$ :

$$
d \mu=d \mu_{1}-d \mu_{2}+\mathrm{i}\left(d \mu_{3}-d \mu_{4}\right) .
$$

Let

$$
F(z)=\int_{\mathbb{R}} \frac{d \mu}{\lambda-z}
$$

be the Borel transform of a complex measure. Show that $\mu$ is uniquely determined by $F$ via the Stieltjes inversion formula

$$
\frac{1}{2}\left(\mu\left(\left(\lambda_{1}, \lambda_{2}\right)\right)+\mu\left(\left[\lambda_{1}, \lambda_{2}\right]\right)\right)=\lim _{\varepsilon \downarrow 0} \frac{1}{2 \pi \mathrm{i}} \int_{\lambda_{1}}^{\lambda_{2}}(F(\lambda+\mathrm{i} \varepsilon)-F(\lambda-\mathrm{i} \varepsilon)) d \lambda .
$$

Problem 3.22. Compute the Borel transform of the complex measure given by $d \mu(\lambda)=\frac{d \lambda}{(\lambda-\mathrm{i})^{2}}$.

## Applications of the spectral theorem

This chapter can be mostly skipped on first reading. You might want to have a look at the first section and then come back to the remaining ones later.

Now let us show how the spectral theorem can be used. We will give a few typical applications:

First we will derive an operator-valued version of the Stieltjes inversion formula. To do this, we need to show how to integrate a family of functions of $A$ with respect to a parameter. Moreover, we will show that these integrals can be evaluated by computing the corresponding integrals of the complexvalued functions.

Secondly we will consider commuting operators and show how certain facts, which are known to hold for the resolvent of an operator $A$, can be established for a larger class of functions.

Then we will show how the eigenvalues below the essential spectrum and dimension of $\operatorname{Ran} P_{A}(\Omega)$ can be estimated using the quadratic form.

Finally, we will investigate tensor products of operators.

### 4.1. Integral formulas

We begin with the first task by having a closer look at the projections $P_{A}(\Omega)$. They project onto subspaces corresponding to expectation values in the set $\Omega$. In particular, the number

$$
\begin{equation*}
\left\langle\psi, \chi_{\Omega}(A) \psi\right\rangle \tag{4.1}
\end{equation*}
$$

is the probability for a measurement of $a$ to lie in $\Omega$. In addition, we have

$$
\begin{equation*}
\langle\psi, A \psi\rangle=\int_{\Omega} \lambda d \mu_{\psi}(\lambda) \in \operatorname{hull}(\Omega), \quad \psi \in P_{A}(\Omega) \mathfrak{H},\|\psi\|=1 \tag{4.2}
\end{equation*}
$$

where hull $(\Omega)$ is the convex hull of $\Omega$.
The space $\operatorname{Ran} \chi_{\left\{\lambda_{0}\right\}}(A)$ is called the eigenspace corresponding to $\lambda_{0}$ since we have

$$
\begin{equation*}
\langle\varphi, A \psi\rangle=\int_{\mathbb{R}} \lambda \chi_{\left\{\lambda_{0}\right\}}(\lambda) d \mu_{\varphi, \psi}(\lambda)=\lambda_{0} \int_{\mathbb{R}} d \mu_{\varphi, \psi}(\lambda)=\lambda_{0}\langle\varphi, \psi\rangle \tag{4.3}
\end{equation*}
$$

and hence $A \psi=\lambda_{0} \psi$ for all $\psi \in \operatorname{Ran} \chi_{\left\{\lambda_{0}\right\}}(A)$. The dimension of the eigenspace is called the multiplicity of the eigenvalue.

Moreover, since

$$
\begin{equation*}
\lim _{\varepsilon \downarrow 0} \frac{-\mathrm{i} \varepsilon}{\lambda-\lambda_{0}-\mathrm{i} \varepsilon}=\chi_{\left\{\lambda_{0}\right\}}(\lambda), \tag{4.4}
\end{equation*}
$$

we infer from Theorem 3.1 that

$$
\begin{equation*}
\lim _{\varepsilon \downarrow 0}-\mathrm{i} \varepsilon R_{A}\left(\lambda_{0}+\mathrm{i} \varepsilon\right) \psi=\chi_{\left\{\lambda_{0}\right\}}(A) \psi . \tag{4.5}
\end{equation*}
$$

Similarly, we can obtain an operator-valued version of the Stieltjes inversion formula. But first we need to recall a few facts from integration in Banach spaces.

We will consider the case of mappings $f: I \rightarrow X$ where $I=\left[t_{0}, t_{1}\right] \subset \mathbb{R}$ is a compact interval and $X$ is a Banach space. As before, a function $f: I \rightarrow X$ is called simple if the image of $f$ is finite, $f(I)=\left\{x_{i}\right\}_{i=1}^{n}$, and if each inverse image $f^{-1}\left(x_{i}\right), 1 \leq i \leq n$, is a Borel set. The set of simple functions $S(I, X)$ forms a linear space and can be equipped with the sup norm

$$
\begin{equation*}
\|f\|_{\infty}=\sup _{t \in I}\|f(t)\| . \tag{4.6}
\end{equation*}
$$

The corresponding Banach space obtained after completion is called the set of regulated functions $R(I, X)$.

Observe that $C(I, X) \subset R(I, X)$. In fact, consider the simple function $f_{n}=\sum_{i=0}^{n-1} f\left(s_{i}\right) \chi_{\left[s_{i}, s_{i+1}\right)}$, where $s_{i}=t_{0}+i \frac{t_{1}-t_{0}}{n}$. Since $f \in C(I, X)$ is uniformly continuous, we infer that $f_{n}$ converges uniformly to $f$.

For $f \in S(I, X)$ we can define a linear map $\int: S(I, X) \rightarrow X$ by

$$
\begin{equation*}
\int_{I} f(t) d t=\sum_{i=1}^{n} x_{i}\left|f^{-1}\left(x_{i}\right)\right| \tag{4.7}
\end{equation*}
$$

where $|\Omega|$ denotes the Lebesgue measure of $\Omega$. This map satisfies

$$
\begin{equation*}
\left\|\int_{I} f(t) d t\right\| \leq\|f\|_{\infty}\left(t_{1}-t_{0}\right) \tag{4.8}
\end{equation*}
$$

and hence it can be extended uniquely to a linear map $\int: R(I, X) \rightarrow X$ with the same norm $\left(t_{1}-t_{0}\right)$ by Theorem 0.26 . We even have

$$
\begin{equation*}
\left\|\int_{I} f(t) d t\right\| \leq \int_{I}\|f(t)\| d t \tag{4.9}
\end{equation*}
$$

which clearly holds for $f \in S(I, X)$ and thus for all $f \in R(I, X)$ by continuity. In addition, if $\ell \in X^{*}$ is a continuous linear functional, then

$$
\begin{equation*}
\ell\left(\int_{I} f(t) d t\right)=\int_{I} \ell(f(t)) d t, \quad f \in R(I, X) . \tag{4.10}
\end{equation*}
$$

In particular, if $A(t) \in R(I, \mathfrak{L}(\mathfrak{H}))$, then

$$
\begin{equation*}
\left(\int_{I} A(t) d t\right) \psi=\int_{I}(A(t) \psi) d t . \tag{4.11}
\end{equation*}
$$

If $I=\mathbb{R}$, we say that $f: I \rightarrow X$ is integrable if $f \in R([-r, r], X)$ for all $r>0$ and if $\|f(t)\|$ is integrable. In this case we can set

$$
\begin{equation*}
\int_{\mathbb{R}} f(t) d t=\lim _{r \rightarrow \infty} \int_{[-r, r]} f(t) d t \tag{4.12}
\end{equation*}
$$

and (4.9) and (4.10) still hold.
We will use the standard notation $\int_{t_{2}}^{t_{3}} f(s) d s=\int_{I} \chi_{\left(t_{2}, t_{3}\right)}(s) f(s) d s$ and $\int_{t_{3}}^{t_{2}} f(s) d s=-\int_{t_{2}}^{t_{3}} f(s) d s$.

We write $f \in C^{1}(I, X)$ if

$$
\begin{equation*}
\frac{d}{d t} f(t)=\lim _{\varepsilon \rightarrow 0} \frac{f(t+\varepsilon)-f(t)}{\varepsilon} \tag{4.13}
\end{equation*}
$$

exists for all $t \in I$. In particular, if $f \in C(I, X)$, then $F(t)=\int_{t_{0}}^{t} f(s) d s \in$ $C^{1}(I, X)$ and $d F / d t=f$ as can be seen from
$\|F(t+\varepsilon)-F(t)-f(t) \varepsilon\|=\left\|\int_{t}^{t+\varepsilon}(f(s)-f(t)) d s\right\| \leq|\varepsilon| \sup _{s \in[t, t+\varepsilon]}\|f(s)-f(t)\|$.
The important facts for us are the following two results.
Lemma 4.1. Suppose $f: I \times \mathbb{R} \rightarrow \mathbb{C}$ is a bounded Borel function and set $F(\lambda)=\int_{I} f(t, \lambda) d t$. Let $A$ be self-adjoint. Then $f(t, A) \in R(I, \mathfrak{L}(\mathfrak{H}))$ and

$$
\begin{equation*}
F(A)=\int_{I} f(t, A) d t, \quad \text { respectively, } \quad F(A) \psi=\int_{I} f(t, A) \psi d t \tag{4.15}
\end{equation*}
$$

Proof. That $f(t, A) \in R(I, \mathfrak{L}(\mathfrak{H}))$ follows from the spectral theorem, since it is no restriction to assume that $A$ is multiplication by $\lambda$ in some $L^{2}$ space.

We compute

$$
\begin{aligned}
\left\langle\varphi,\left(\int_{I} f(t, A) d t\right) \psi\right\rangle & =\int_{I}\langle\varphi, f(t, A) \psi\rangle d t \\
& =\int_{I} \int_{\mathbb{R}} f(t, \lambda) d \mu_{\varphi, \psi}(\lambda) d t \\
& =\int_{\mathbb{R}} \int_{I} f(t, \lambda) d t d \mu_{\varphi, \psi}(\lambda) \\
& =\int_{\mathbb{R}} F(\lambda) d \mu_{\varphi, \psi}(\lambda)=\langle\varphi, F(A) \psi\rangle
\end{aligned}
$$

by Fubini's theorem and hence the first claim follows.
Lemma 4.2. Suppose $f: \mathbb{R} \rightarrow \mathfrak{L}(\mathfrak{H})$ is integrable and $A \in \mathfrak{L}(\mathfrak{H})$. Then

$$
\begin{equation*}
A \int_{\mathbb{R}} f(t) d t=\int_{\mathbb{R}} A f(t) d t, \quad \text { respectively, } \quad \int_{\mathbb{R}} f(t) d t A=\int_{\mathbb{R}} f(t) A d t . \tag{4.16}
\end{equation*}
$$

Proof. It suffices to prove the case where $f$ is simple and of compact support. But for such functions the claim is straightforward.

Now we can prove an operator-valued version of the Stieltjes inversion formula.

Theorem 4.3 (Stone's formula). Let $A$ be self-adjoint. Then

$$
\begin{equation*}
\frac{1}{2 \pi \mathrm{i}} \int_{\lambda_{1}}^{\lambda_{2}}\left(R_{A}(\lambda+\mathrm{i} \varepsilon)-R_{A}(\lambda-\mathrm{i} \varepsilon)\right) d \lambda \xrightarrow{s} \frac{1}{2}\left(P_{A}\left(\left[\lambda_{1}, \lambda_{2}\right]\right)+P_{A}\left(\left(\lambda_{1}, \lambda_{2}\right)\right)\right) \tag{4.17}
\end{equation*}
$$

strongly.
Proof. By

$$
\begin{aligned}
& \frac{1}{2 \pi \mathrm{i}} \int_{\lambda_{1}}^{\lambda_{2}}\left(\frac{1}{x-\lambda-\mathrm{i} \varepsilon}-\frac{1}{x-\lambda+\mathrm{i} \varepsilon}\right) d \lambda=\frac{1}{\pi} \int_{\lambda_{1}}^{\lambda_{2}} \frac{\varepsilon}{(x-\lambda)^{2}+\varepsilon^{2}} d \lambda \\
& \quad=\frac{1}{\pi}\left(\arctan \left(\frac{\lambda_{2}-x}{\varepsilon}\right)-\arctan \left(\frac{\lambda_{1}-x}{\varepsilon}\right)\right) \\
& \quad \rightarrow \frac{1}{2}\left(\chi_{\left[\lambda_{1}, \lambda_{2}\right]}(x)+\chi_{\left(\lambda_{1}, \lambda_{2}\right)}(x)\right)
\end{aligned}
$$

the result follows combining the last part of Theorem 3.1 with Lemma 4.1.

Note that by using the first resolvent formula, Stone's formula can also be written in the form

$$
\begin{align*}
\left\langle\psi, \frac{1}{2}\left(P_{A}\left(\left[\lambda_{1}, \lambda_{2}\right]\right)+P_{A}\left(\left(\lambda_{1}, \lambda_{2}\right)\right)\right) \psi\right\rangle & =\lim _{\varepsilon \downarrow 0} \frac{1}{\pi} \int_{\lambda_{1}}^{\lambda_{2}} \operatorname{Im}\left\langle\psi, R_{A}(\lambda+\mathrm{i} \varepsilon) \psi\right\rangle d \lambda \\
& =\lim _{\varepsilon \downarrow 0} \frac{\varepsilon}{\pi} \int_{\lambda_{1}}^{\lambda_{2}}\left\|R_{A}(\lambda+\mathrm{i} \varepsilon) \psi\right\|^{2} d \lambda . \tag{4.18}
\end{align*}
$$

Problem 4.1. Let $\Gamma$ be a differentiable Jordan curve in $\rho(A)$. Show

$$
\chi_{\Omega}(A)=\int_{\Gamma} R_{A}(z) d z,
$$

where $\Omega$ is the intersection of the interior of $\Gamma$ with $\mathbb{R}$.

### 4.2. Commuting operators

Now we come to commuting operators. As a preparation we can now prove
Lemma 4.4. Let $K \subseteq \mathbb{R}$ be closed and let $C_{\infty}(K)$ be the set of all continuous functions on $K$ which vanish at $\infty$ (if $K$ is unbounded) with the sup norm. The *-subalgebra generated by the function

$$
\begin{equation*}
\lambda \mapsto \frac{1}{\lambda-z} \tag{4.19}
\end{equation*}
$$

for one $z \in \mathbb{C} \backslash K$ is dense in $C_{\infty}(K)$.
Proof. If $K$ is compact, the claim follows directly from the complex StoneWeierstraß theorem since $\left(\lambda_{1}-z\right)^{-1}=\left(\lambda_{2}-z\right)^{-1}$ implies $\lambda_{1}=\lambda_{2}$. Otherwise, replace $K$ by $\tilde{K}=K \cup\{\infty\}$, which is compact, and set $(\infty-z)^{-1}=0$. Then we can again apply the complex Stone-Weierstraß theorem to conclude that our $*$-subalgebra is equal to $\{f \in C(\tilde{K}) \mid f(\infty)=0\}$ which is equivalent to $C_{\infty}(K)$.

We say that two bounded operators $A, B$ commute if

$$
\begin{equation*}
[A, B]=A B-B A=0 . \tag{4.20}
\end{equation*}
$$

If $A$ or $B$ is unbounded, we soon run into trouble with this definition since the above expression might not even make sense for any nonzero vector (e.g., take $B=\langle\varphi,.\rangle \psi$ with $\psi \notin \mathfrak{D}(A))$. To avoid this nuisance, we will replace $A$ by a bounded function of $A$. A good candidate is the resolvent. Hence if $A$ is self-adjoint and $B$ is bounded, we will say that $A$ and $B$ commute if

$$
\begin{equation*}
\left[R_{A}(z), B\right]=\left[R_{A}\left(z^{*}\right), B\right]=0 \tag{4.21}
\end{equation*}
$$

for one $z \in \rho(A)$.

Lemma 4.5. Suppose $A$ is self-adjoint and commutes with the bounded operator B. Then

$$
\begin{equation*}
[f(A), B]=0 \tag{4.22}
\end{equation*}
$$

for any bounded Borel function $f$. If $f$ is unbounded, the claim holds for any $\psi \in \mathfrak{D}(f(A))$ in the sense that $B f(A) \subseteq f(A) B$.

Proof. Equation (4.21) tells us that (4.22) holds for any $f$ in the $*$-subalgebra generated by $R_{A}(z)$. Since this subalgebra is dense in $C_{\infty}(\sigma(A))$, the claim follows for all such $f \in C_{\infty}(\sigma(A))$. Next fix $\psi \in \mathfrak{H}$ and let $f$ be bounded. Choose a sequence $f_{n} \in C_{\infty}(\sigma(A))$ converging to $f$ in $L^{2}\left(\mathbb{R}, d \mu_{\psi}\right)$. Then

$$
B f(A) \psi=\lim _{n \rightarrow \infty} B f_{n}(A) \psi=\lim _{n \rightarrow \infty} f_{n}(A) B \psi=f(A) B \psi .
$$

If $f$ is unbounded, let $\psi \in \mathfrak{D}(f(A))$ and choose $f_{n}$ as in (3.26). Then

$$
f(A) B \psi=\lim _{n \rightarrow \infty} f_{n}(A) B \psi=\lim _{n \rightarrow \infty} B f_{n}(A) \psi
$$

shows $f \in L^{2}\left(\mathbb{R}, d \mu_{B \psi}\right)$ (i.e., $B \psi \in \mathfrak{D}(f(A))$ ) and $f(A) B \psi=B F(A) \psi$.
In the special case where $B$ is an orthogonal projection, we obtain
Corollary 4.6. Let $A$ be self-adjoint and $\mathfrak{H}_{1}$ a closed subspace with corresponding projector $P_{1}$. Then $\mathfrak{H}_{1}$ reduces $A$ if and only if $P_{1}$ and $A$ commute.

Furthermore, note
Corollary 4.7. If $A$ is self-adjoint and bounded, then (4.21) holds if and only if (4.20) holds.

Proof. Since $\sigma(A)$ is compact, we have $\lambda \in C_{\infty}(\sigma(A))$ and hence (4.20) follows from (4.22) by our lemma. Conversely, since $B$ commutes with any polynomial of $A$, the claim follows from the Neumann series.

As another consequence we obtain
Theorem 4.8. Suppose $A$ is self-adjoint and has simple spectrum. A bounded operator $B$ commutes with $A$ if and only if $B=f(A)$ for some bounded Borel function.

Proof. Let $\psi$ be a cyclic vector for $A$. By our unitary equivalence it is no restriction to assume $\mathfrak{H}=L^{2}\left(\mathbb{R}, d \mu_{\psi}\right)$. Then

$$
B g(\lambda)=B g(\lambda) \cdot 1=g(\lambda)(B 1)(\lambda)
$$

since $B$ commutes with the multiplication operator $g(\lambda)$. Hence $B$ is multiplication by $f(\lambda)=(B 1)(\lambda)$.

The assumption that the spectrum of $A$ is simple is crucial as the example $A=\mathbb{I}$ shows. Note also that the functions $\exp (-\mathrm{i} t A)$ can also be used instead of resolvents.

Lemma 4.9. Suppose $A$ is self-adjoint and $B$ is bounded. Then $B$ commutes with $A$ if and only if

$$
\begin{equation*}
\left[\mathrm{e}^{-\mathrm{i} A t}, B\right]=0 \tag{4.23}
\end{equation*}
$$

for all $t \in \mathbb{R}$.
Proof. It suffices to show $[\hat{f}(A), B]=0$ for $f \in \mathcal{S}(\mathbb{R})$, since these functions are dense in $C_{\infty}(\mathbb{R})$ by the complex Stone-Weierstraß theorem. Here $\hat{f}$ denotes the Fourier transform of $f$; see Section 7.1. But for such $f$ we have

$$
[\hat{f}(A), B]=\frac{1}{\sqrt{2 \pi}}\left[\int_{\mathbb{R}} f(t) \mathrm{e}^{-\mathrm{i} A t} d t, B\right]=\frac{1}{\sqrt{2 \pi}} \int_{\mathbb{R}} f(t)\left[\mathrm{e}^{-\mathrm{i} A t}, B\right] d t=0
$$

by Lemma 4.2.
The extension to the case where $B$ is self-adjoint and unbounded is straightforward. We say that $A$ and $B$ commute in this case if

$$
\begin{equation*}
\left[R_{A}\left(z_{1}\right), R_{B}\left(z_{2}\right)\right]=\left[R_{A}\left(z_{1}^{*}\right), R_{B}\left(z_{2}\right)\right]=0 \tag{4.24}
\end{equation*}
$$

for one $z_{1} \in \rho(A)$ and one $z_{2} \in \rho(B)$ (the claim for $z_{2}^{*}$ follows by taking adjoints). From our above analysis it follows that this is equivalent to

$$
\begin{equation*}
\left[\mathrm{e}^{-\mathrm{i} A t}, \mathrm{e}^{-\mathrm{i} B s}\right]=0, \quad t, s \in \mathbb{R}, \tag{4.25}
\end{equation*}
$$

respectively,

$$
\begin{equation*}
[f(A), g(B)]=0 \tag{4.26}
\end{equation*}
$$

for arbitrary bounded Borel functions $f$ and $g$.
Problem 4.2. Let $A$ and $B$ be self-adjoint. Show that $A$ and $B$ commute if and only if the corresponding spectral projections $P_{A}(\Omega)$ and $P_{B}(\Omega)$ commute for every Borel set $\Omega$. In particular, $\operatorname{Ran}\left(P_{B}(\Omega)\right)$ reduces $A$ and vice versa.
Problem 4.3. Let $A$ and $B$ be self-adjoint operators with pure point spectrum. Show that $A$ and $B$ commute if and only if they have a common orthonormal basis of eigenfunctions.

### 4.3. The min-max theorem

In many applications a self-adjoint operator has a number of eigenvalues below the bottom of the essential spectrum. The essential spectrum is obtained from the spectrum by removing all discrete eigenvalues with finite multiplicity (we will have a closer look at this in Section 6.2). In general there is no way of computing the lowest eigenvalues and their corresponding eigenfunctions explicitly. However, one often has some idea about how the eigenfunctions might approximately look.

So suppose we have a normalized function $\psi_{1}$ which is an approximation for the eigenfunction $\varphi_{1}$ of the lowest eigenvalue $E_{1}$. Then by Theorem 2.19 we know that

$$
\begin{equation*}
\left\langle\psi_{1}, A \psi_{1}\right\rangle \geq\left\langle\varphi_{1}, A \varphi_{1}\right\rangle=E_{1} . \tag{4.27}
\end{equation*}
$$

If we add some free parameters to $\psi_{1}$, one can optimize them and obtain quite good upper bounds for the first eigenvalue.

But is there also something one can say about the next eigenvalues? Suppose we know the first eigenfunction $\varphi_{1}$. Then we can restrict $A$ to the orthogonal complement of $\varphi_{1}$ and proceed as before: $E_{2}$ will be the infimum over all expectations restricted to this subspace. If we restrict to the orthogonal complement of an approximating eigenfunction $\psi_{1}$, there will still be a component in the direction of $\varphi_{1}$ left and hence the infimum of the expectations will be lower than $E_{2}$. Thus the optimal choice $\psi_{1}=\varphi_{1}$ will give the maximal value $E_{2}$.

More precisely, let $\left\{\varphi_{j}\right\}_{j=1}^{N}$ be an orthonormal basis for the space spanned by the eigenfunctions corresponding to eigenvalues below the essential spectrum. Here the essential spectrum $\sigma_{\text {ess }}(A)$ is given by precisely those values in the spectrum which are not isolated eigenvalues of finite multiplicity (see Section 6.2). Assume they satisfy $\left(A-E_{j}\right) \varphi_{j}=0$, where $E_{j} \leq E_{j+1}$ are the eigenvalues (counted according to their multiplicity). If the number of eigenvalues $N$ is finite, we set $E_{j}=\inf \sigma_{e s s}(A)$ for $j>N$ and choose $\varphi_{j}$ orthonormal such that $\left\|\left(A-E_{j}\right) \varphi_{j}\right\| \leq \varepsilon$.

Define

$$
\begin{equation*}
U\left(\psi_{1}, \ldots, \psi_{n}\right)=\left\{\psi \in \mathfrak{D}(A) \mid\|\psi\|=1, \psi \in \operatorname{span}\left\{\psi_{1}, \ldots, \psi_{n}\right\}^{\perp}\right\} . \tag{4.28}
\end{equation*}
$$

(i) We have

$$
\begin{equation*}
\inf _{\psi \in U\left(\psi_{1}, \ldots, \psi_{n-1}\right)}\langle\psi, A \psi\rangle \leq E_{n}+O(\varepsilon) . \tag{4.29}
\end{equation*}
$$

In fact, set $\psi=\sum_{j=1}^{n} \alpha_{j} \varphi_{j}$ and choose $\alpha_{j}$ such that $\psi \in U\left(\psi_{1}, \ldots, \psi_{n-1}\right)$. Then

$$
\begin{equation*}
\langle\psi, A \psi\rangle=\sum_{j=1}^{n}\left|\alpha_{j}\right|^{2} E_{j}+O(\varepsilon) \leq E_{n}+O(\varepsilon) \tag{4.30}
\end{equation*}
$$

and the claim follows.
(ii) We have

$$
\begin{equation*}
\inf _{\psi \in U\left(\varphi_{1}, \ldots, \varphi_{n-1}\right)}\langle\psi, A \psi\rangle \geq E_{n}-O(\varepsilon) . \tag{4.31}
\end{equation*}
$$

In fact, set $\psi=\varphi_{n}$.
Since $\varepsilon$ can be chosen arbitrarily small, we have proven the following.

Theorem 4.10 (Min-max). Let $A$ be self-adjoint and let $E_{1} \leq E_{2} \leq E_{3} \ldots$ be the eigenvalues of $A$ below the essential spectrum, respectively, the infimum of the essential spectrum, once there are no more eigenvalues left. Then

$$
\begin{equation*}
E_{n}=\sup _{\psi_{1}, \ldots, \psi_{n-1}} \inf _{\psi \in U\left(\psi_{1}, \ldots, \psi_{n-1}\right)}\langle\psi, A \psi\rangle . \tag{4.32}
\end{equation*}
$$

Clearly the same result holds if $\mathfrak{D}(A)$ is replaced by the quadratic form domain $\mathfrak{Q}(A)$ in the definition of $U$. In addition, as long as $E_{n}$ is an eigenvalue, the sup and inf are in fact max and min, explaining the name.

Corollary 4.11. Suppose $A$ and $B$ are self-adjoint operators with $A \geq B$ (i.e., $A-B \geq 0$ ). Then $E_{n}(A) \geq E_{n}(B)$.

Problem 4.4. Suppose $A, A_{n}$ are bounded and $A_{n} \rightarrow A$. Then $E_{k}\left(A_{n}\right) \rightarrow$ $E_{k}(A)$. (Hint: $\left\|A-A_{n}\right\| \leq \varepsilon$ is equivalent to $A-\varepsilon \leq A \leq A+\varepsilon$.)

### 4.4. Estimating eigenspaces

Next, we show that the dimension of the range of $P_{A}(\Omega)$ can be estimated if we have some functions which lie approximately in this space.

Theorem 4.12. Suppose $A$ is a self-adjoint operator and $\psi_{j}, 1 \leq j \leq k$, are linearly independent elements of a $\mathfrak{H}$.
(i) Let $\lambda \in \mathbb{R}, \psi_{j} \in \mathfrak{Q}(A)$. If

$$
\begin{equation*}
\langle\psi, A \psi\rangle<\lambda\|\psi\|^{2} \tag{4.33}
\end{equation*}
$$

for any nonzero linear combination $\psi=\sum_{j=1}^{k} c_{j} \psi_{j}$, then

$$
\begin{equation*}
\operatorname{dim} \operatorname{Ran} P_{A}((-\infty, \lambda)) \geq k \tag{4.34}
\end{equation*}
$$

Similarly, $\langle\psi, A \psi\rangle>\lambda\|\psi\|^{2}$ implies $\operatorname{dim} \operatorname{Ran} P_{A}((\lambda, \infty)) \geq k$.
(ii) Let $\lambda_{1}<\lambda_{2}, \psi_{j} \in \mathfrak{D}(A)$. If

$$
\begin{equation*}
\left\|\left(A-\frac{\lambda_{2}+\lambda_{1}}{2}\right) \psi\right\|<\frac{\lambda_{2}-\lambda_{1}}{2}\|\psi\| \tag{4.35}
\end{equation*}
$$

for any nonzero linear combination $\psi=\sum_{j=1}^{k} c_{j} \psi_{j}$, then

$$
\begin{equation*}
\operatorname{dim} \operatorname{Ran} P_{A}\left(\left(\lambda_{1}, \lambda_{2}\right)\right) \geq k \tag{4.36}
\end{equation*}
$$

Proof. (i) Let $M=\operatorname{span}\left\{\psi_{j}\right\} \subseteq \mathfrak{H}$. We claim $\operatorname{dim} P_{A}((-\infty, \lambda)) M=$ $\operatorname{dim} M=k$. For this it suffices to show $\left.\operatorname{Ker} P_{A}((-\infty, \lambda))\right|_{M}=\{0\}$. Suppose $P_{A}((-\infty, \lambda)) \psi=0, \psi \neq 0$. Then we see that for any nonzero linear
combination $\psi$

$$
\begin{aligned}
\langle\psi, A \psi\rangle & =\int_{\mathbb{R}} \eta d \mu_{\psi}(\eta)=\int_{[\lambda, \infty)} \eta d \mu_{\psi}(\eta) \\
& \geq \lambda \int_{[\lambda, \infty)} d \mu_{\psi}(\eta)=\lambda\|\psi\|^{2} .
\end{aligned}
$$

This contradicts our assumption (4.33).
(ii) This is just the previous case (i) applied to $\left(A-\left(\lambda_{2}+\lambda_{1}\right) / 2\right)^{2}$ with $\lambda=\left(\lambda_{2}-\lambda_{1}\right)^{2} / 4$.

Another useful estimate is
Theorem 4.13 (Temple's inequality). Let $\lambda_{1}<\lambda_{2}$ and $\psi \in \mathfrak{D}(A)$ with $\|\psi\|=1$ such that

$$
\begin{equation*}
\lambda=\langle\psi, A \psi\rangle \in\left(\lambda_{1}, \lambda_{2}\right) . \tag{4.37}
\end{equation*}
$$

If there is one isolated eigenvalue $E$ between $\lambda_{1}$ and $\lambda_{2}$, that is, $\sigma(A) \cap$ $\left(\lambda_{1}, \lambda_{2}\right)=E$, then

$$
\begin{equation*}
\lambda-\frac{\|(A-\lambda) \psi\|^{2}}{\lambda_{2}-\lambda} \leq E \leq \lambda+\frac{\|(A-\lambda) \psi\|^{2}}{\lambda-\lambda_{1}} . \tag{4.38}
\end{equation*}
$$

Proof. First of all we can assume $\lambda=0$ if we replace $A$ by $A-\lambda$. To prove the first inequality, observe that by assumption $\left(E, \lambda_{2}\right) \subset \rho(A)$ and hence the spectral theorem implies $\left(A-\lambda_{2}\right)(A-E) \geq 0$. Thus $\left\langle\psi,\left(A-\lambda_{2}\right)(A-E)\right\rangle=$ $\|A \psi\|^{2}+\lambda_{2} E \geq 0$ and the first inequality follows after dividing by $\lambda_{2}>0$. Similarly, $\left(A-\lambda_{1}\right)(A-E) \geq 0$ implies the second inequality.

Note that the last inequality only provides additional information if $\|(A-\lambda) \psi\|^{2} \leq\left(\lambda_{2}-\lambda\right)\left(\lambda-\lambda_{1}\right)$.

A typical application is if $E=E_{0}$ is the lowest eigenvalue. In this case any normalized trial function $\psi$ will give the bound $E_{0} \leq\langle\psi, A \psi\rangle$. If, in addition, we also have some estimate $\lambda_{2} \leq E_{1}$ for the second eigenvalue $E_{1}$, then Temple's inequality can give a bound from below. For $\lambda_{1}$ we can choose any value $\lambda_{1}<E_{0}$; in fact, if we let $\lambda_{1} \rightarrow-\infty$, we just recover the bound we already know.

### 4.5. Tensor products of operators

Recall the definition of the tensor product of Hilbert space from Section 1.4. Suppose $A_{j}, 1 \leq j \leq n$, are (essentially) self-adjoint operators on $\mathfrak{H}_{j}$. For every monomial $\lambda_{1}^{n_{1}} \cdots \lambda_{n}^{n_{n}}$ we can define

$$
\begin{equation*}
\left(A_{1}^{n_{1}} \otimes \cdots \otimes A_{n}^{n_{n}}\right) \psi_{1} \otimes \cdots \otimes \psi_{n}=\left(A_{1}^{n_{1}} \psi_{1}\right) \otimes \cdots \otimes\left(A_{n}^{n_{n}} \psi_{n}\right), \psi_{j} \in \mathfrak{D}\left(A_{j}^{n_{j}}\right), \tag{4.39}
\end{equation*}
$$

and extend this definition by linearity to the span of all such functions (check that this definition is well-defined by showing that the corresponding operator on $\mathcal{F}\left(\mathfrak{H}_{1}, \ldots, \mathfrak{H}_{n}\right)$ vanishes on $\left.\mathcal{N}\left(\mathfrak{H}_{1}, \ldots, \mathfrak{H}_{n}\right)\right)$. Hence for every polynomial $P\left(\lambda_{1}, \ldots, \lambda_{n}\right)$ of degree $N$ we obtain an operator

$$
\begin{equation*}
P\left(A_{1}, \ldots, A_{n}\right) \psi_{1} \otimes \cdots \otimes \psi_{n}, \quad \psi_{j} \in \mathfrak{D}\left(A_{j}^{N}\right) \tag{4.40}
\end{equation*}
$$

defined on the set

$$
\begin{equation*}
\mathfrak{D}=\operatorname{span}\left\{\psi_{1} \otimes \cdots \otimes \psi_{n} \mid \psi_{j} \in \mathfrak{D}\left(A_{j}^{N}\right)\right\} . \tag{4.41}
\end{equation*}
$$

Moreover, if $P$ is real-valued, then the operator $P\left(A_{1}, \ldots, A_{n}\right)$ on $\mathfrak{D}$ is symmetric and we can consider its closure, which will again be denoted by $P\left(A_{1}, \ldots, A_{n}\right)$.

Theorem 4.14. Suppose $A_{j}, 1 \leq j \leq n$, are self-adjoint operators on $\mathfrak{H}_{j}$ and let $P\left(\lambda_{1}, \ldots, \lambda_{n}\right)$ be a real-valued polynomial and define $P\left(A_{1}, \ldots, A_{n}\right)$ as above.

Then $P\left(A_{1}, \ldots, A_{n}\right)$ is self-adjoint and its spectrum is the closure of the range of $P$ on the product of the spectra of the $A_{j}$; that is,

$$
\begin{equation*}
\sigma\left(P\left(A_{1}, \ldots, A_{n}\right)\right)=\overline{P\left(\sigma\left(A_{1}\right), \ldots, \sigma\left(A_{n}\right)\right)} \tag{4.42}
\end{equation*}
$$

Proof. By the spectral theorem it is no restriction to assume that $A_{j}$ is multiplication by $\lambda_{j}$ on $L^{2}\left(\mathbb{R}, d \mu_{j}\right)$ and $P\left(A_{1}, \ldots, A_{n}\right)$ is hence multiplication by $P\left(\lambda_{1}, \ldots, \lambda_{n}\right)$ on $L^{2}\left(\mathbb{R}^{n}, d \mu_{1} \times \cdots \times d \mu_{n}\right)$. Since $\mathfrak{D}$ contains the set of all functions $\psi_{1}\left(\lambda_{1}\right) \cdots \psi_{n}\left(\lambda_{n}\right)$ for which $\psi_{j} \in L_{c}^{2}\left(\mathbb{R}, d \mu_{j}\right)$, it follows that the domain of the closure of $P$ contains $L_{c}^{2}\left(\mathbb{R}^{n}, d \mu_{1} \times \cdots \times d \mu_{n}\right)$. Hence $P$ is the maximally defined multiplication operator by $P\left(\lambda_{1}, \ldots, \lambda_{n}\right)$, which is self-adjoint.

Now let $\lambda=P\left(\lambda_{1}, \ldots, \lambda_{n}\right)$ with $\lambda_{j} \in \sigma\left(A_{j}\right)$. Then there exist Weyl sequences $\psi_{j, k} \in \mathfrak{D}\left(A_{j}^{N}\right)$ with $\left(A_{j}-\lambda_{j}\right) \psi_{j, k} \rightarrow 0$ as $k \rightarrow \infty$. Consequently, $(P-\lambda) \psi_{k} \rightarrow 0$, where $\psi_{k}=\psi_{1, k} \otimes \cdots \otimes \psi_{1, k}$ and hence $\lambda \in \sigma(P)$. Conversely, if $\lambda \notin \overline{P\left(\sigma\left(A_{1}\right), \ldots, \sigma\left(A_{n}\right)\right)}$, then $\left|P\left(\lambda_{1}, \ldots, \lambda_{n}\right)-\lambda\right| \geq \varepsilon$ for a.e. $\lambda_{j}$ with respect to $\mu_{j}$ and hence $(P-\lambda)^{-1}$ exists and is bounded; that is, $\lambda \in$ $\rho(P)$.

The two main cases of interest are $A_{1} \otimes A_{2}$, in which case

$$
\begin{equation*}
\sigma\left(A_{1} \otimes A_{2}\right)=\overline{\sigma\left(A_{1}\right) \sigma\left(A_{2}\right)}=\overline{\left\{\lambda_{1} \lambda_{2} \mid \lambda_{j} \in \sigma\left(A_{j}\right)\right\}} \tag{4.43}
\end{equation*}
$$

and $A_{1} \otimes \mathbb{I}+\mathbb{I} \otimes A_{2}$, in which case

$$
\begin{equation*}
\sigma\left(A_{1} \otimes \mathbb{I}+\mathbb{I} \otimes A_{2}\right)=\overline{\sigma\left(A_{1}\right)+\sigma\left(A_{2}\right)}=\overline{\left\{\lambda_{1}+\lambda_{2} \mid \lambda_{j} \in \sigma\left(A_{j}\right)\right\}} . \tag{4.44}
\end{equation*}
$$

Problem 4.5. Show that the closure can be omitted in (4.44) if at least one operator is bounded and in (4.43) if both operators are bounded.

## Quantum dynamics

As in the finite dimensional case, the solution of the Schrödinger equation

$$
\begin{equation*}
\mathrm{i} \frac{d}{d t} \psi(t)=H \psi(t) \tag{5.1}
\end{equation*}
$$

is given by

$$
\begin{equation*}
\psi(t)=\exp (-\mathrm{i} t H) \psi(0) \tag{5.2}
\end{equation*}
$$

A detailed investigation of this formula will be our first task. Moreover, in the finite dimensional case the dynamics is understood once the eigenvalues are known and the same is true in our case once we know the spectrum. Note that, like any Hamiltonian system from classical mechanics, our system is not hyperbolic (i.e., the spectrum is not away from the real axis) and hence simple results such as all solutions tend to the equilibrium position cannot be expected.

### 5.1. The time evolution and Stone's theorem

In this section we want to have a look at the initial value problem associated with the Schrödinger equation (2.12) in the Hilbert space $\mathfrak{H}$. If $\mathfrak{H}$ is onedimensional (and hence $A$ is a real number), the solution is given by

$$
\begin{equation*}
\psi(t)=\mathrm{e}^{-\mathrm{i} t A} \psi(0) \tag{5.3}
\end{equation*}
$$

Our hope is that this formula also applies in the general case and that we can reconstruct a one-parameter unitary group $U(t)$ from its generator $A$ (compare (2.11)) via $U(t)=\exp (-\mathrm{i} t A)$. We first investigate the family of operators $\exp (-\mathrm{i} t A)$.

Theorem 5.1. Let $A$ be self-adjoint and let $U(t)=\exp (-\mathrm{i} t A)$.
(i) $U(t)$ is a strongly continuous one-parameter unitary group.
(ii) The limit $\lim _{t \rightarrow 0} \frac{1}{t}(U(t) \psi-\psi)$ exists if and only if $\psi \in \mathfrak{D}(A)$ in which case $\lim _{t \rightarrow 0} \frac{1}{t}(U(t) \psi-\psi)=-\mathrm{i} A \psi$.
(iii) $U(t) \mathfrak{D}(A)=\mathfrak{D}(A)$ and $A U(t)=U(t) A$.

Proof. The group property (i) follows directly from Theorem 3.1 and the corresponding statements for the function $\exp (-i t \lambda)$. To prove strong continuity, observe that

$$
\begin{aligned}
\lim _{t \rightarrow t_{0}}\left\|\mathrm{e}^{-\mathrm{i} t A} \psi-\mathrm{e}^{-\mathrm{i} t_{0} A} \psi\right\|^{2} & =\lim _{t \rightarrow t_{0}} \int_{\mathbb{R}}\left|\mathrm{e}^{-\mathrm{i} \mathrm{t} \lambda}-\mathrm{e}^{-\mathrm{i} t_{0} \lambda}\right|^{2} d \mu_{\psi}(\lambda) \\
& =\int_{\mathbb{R}} \lim _{t \rightarrow t_{0}}\left|\mathrm{e}^{-\mathrm{i} t \lambda}-\mathrm{e}^{-\mathrm{i} t_{0} \lambda}\right|^{2} d \mu_{\psi}(\lambda)=0
\end{aligned}
$$

by the dominated convergence theorem.
Similarly, if $\psi \in \mathfrak{D}(A)$, we obtain

$$
\lim _{t \rightarrow 0}\left\|\frac{1}{t}\left(\mathrm{e}^{-\mathrm{i} t A} \psi-\psi\right)+\mathrm{i} A \psi\right\|^{2}=\lim _{t \rightarrow 0} \int_{\mathbb{R}}\left|\frac{1}{t}\left(\mathrm{e}^{-\mathrm{i} t \lambda}-1\right)+\mathrm{i} \lambda\right|^{2} d \mu_{\psi}(\lambda)=0
$$

since $\left|\mathrm{e}^{\mathrm{i} \lambda \lambda}-1\right| \leq|t \lambda|$. Now let $\tilde{A}$ be the generator defined as in (2.11). Then $\tilde{A}$ is a symmetric extension of $A$ since we have

$$
\langle\varphi, \tilde{A} \psi\rangle=\lim _{t \rightarrow 0}\left\langle\varphi, \frac{\mathrm{i}}{t}(U(t)-1) \psi\right\rangle=\lim _{t \rightarrow 0}\left\langle\frac{\mathrm{i}}{-t}(U(-t)-1) \varphi, \psi\right\rangle=\langle\tilde{A} \varphi, \psi\rangle
$$

and hence $\tilde{A}=A$ by Corollary 2.2. This settles (ii).
To see (iii), replace $\psi \rightarrow U(s) \psi$ in (ii).
For our original problem this implies that formula (5.3) is indeed the solution to the initial value problem of the Schrödinger equation. Moreover,

$$
\begin{equation*}
\langle U(t) \psi, A U(t) \psi\rangle=\langle U(t) \psi, U(t) A \psi\rangle=\langle\psi, A \psi\rangle \tag{5.4}
\end{equation*}
$$

shows that the expectations of $A$ are time independent. This corresponds to conservation of energy.

On the other hand, the generator of the time evolution of a quantum mechanical system should always be a self-adjoint operator since it corresponds to an observable (energy). Moreover, there should be a one-to-one correspondence between the unitary group and its generator. This is ensured by Stone's theorem.

Theorem 5.2 (Stone). Let $U(t)$ be a weakly continuous one-parameter unitary group. Then its generator $A$ is self-adjoint and $U(t)=\exp (-\mathrm{i} t A)$.

Proof. First of all observe that weak continuity together with item (iv) of Lemma 1.12 shows that $U(t)$ is in fact strongly continuous.

Next we show that $A$ is densely defined. Pick $\psi \in \mathfrak{H}$ and set

$$
\psi_{\tau}=\int_{0}^{\tau} U(t) \psi d t
$$

(the integral is defined as in Section 4.1) implying $\lim _{\tau \rightarrow 0} \tau^{-1} \psi_{\tau}=\psi$. Moreover,

$$
\begin{aligned}
\frac{1}{t}\left(U(t) \psi_{\tau}-\psi_{\tau}\right) & =\frac{1}{t} \int_{t}^{t+\tau} U(s) \psi d s-\frac{1}{t} \int_{0}^{\tau} U(s) \psi d s \\
& =\frac{1}{t} \int_{\tau}^{\tau+t} U(s) \psi d s-\frac{1}{t} \int_{0}^{t} U(s) \psi d s \\
& =\frac{1}{t} U(\tau) \int_{0}^{t} U(s) \psi d s-\frac{1}{t} \int_{0}^{t} U(s) \psi d s \rightarrow U(\tau) \psi-\psi
\end{aligned}
$$

as $t \rightarrow 0$ shows $\psi_{\tau} \in \mathfrak{D}(A)$. As in the proof of the previous theorem, we can show that $A$ is symmetric and that $U(t) \mathfrak{D}(A)=\mathfrak{D}(A)$.

Next, let us prove that $A$ is essentially self-adjoint. By Lemma 2.7 it suffices to prove $\operatorname{Ker}\left(A^{*}-z^{*}\right)=\{0\}$ for $z \in \mathbb{C} \backslash \mathbb{R}$. Suppose $A^{*} \varphi=z^{*} \varphi$. Then for each $\psi \in \mathfrak{D}(A)$ we have

$$
\frac{d}{d t}\langle\varphi, U(t) \psi\rangle=\langle\varphi,-\mathrm{i} A U(t) \psi\rangle=-\mathrm{i}\left\langle A^{*} \varphi, U(t) \psi\right\rangle=-\mathrm{i} z\langle\varphi, U(t) \psi\rangle
$$

and hence $\langle\varphi, U(t) \psi\rangle=\exp (-\mathrm{i} z t)\langle\varphi, \psi\rangle$. Since the left-hand side is bounded for all $t \in \mathbb{R}$ and the exponential on the right-hand side is not, we must have $\langle\varphi, \psi\rangle=0$ implying $\varphi=0$ since $\mathfrak{D}(A)$ is dense.

So $A$ is essentially self-adjoint and we can introduce $V(t)=\exp (-\mathrm{i} t \bar{A})$. We are done if we can show $U(t)=V(t)$.

Let $\psi \in \mathfrak{D}(A)$ and abbreviate $\psi(t)=(U(t)-V(t)) \psi$. Then

$$
\lim _{s \rightarrow 0} \frac{\psi(t+s)-\psi(t)}{s}=\mathrm{i} \bar{A} \psi(t)
$$

and hence $\frac{d}{d t}\|\psi(t)\|^{2}=2 \operatorname{Re}\langle\psi(t), \mathrm{i} A \psi(t)\rangle=0$. Since $\psi(0)=0$, we have $\psi(t)=0$ and hence $U(t)$ and $V(t)$ coincide on $\mathfrak{D}(A)$. Furthermore, since $\mathfrak{D}(A)$ is dense, we have $U(t)=V(t)$ by continuity.

As an immediate consequence of the proof we also note the following useful criterion.

Corollary 5.3. Suppose $\mathfrak{D} \subseteq \mathfrak{D}(A)$ is dense and invariant under $U(t)$. Then $A$ is essentially self-adjoint on $\mathfrak{D}$.

Proof. As in the above proof it follows that $\langle\varphi, \psi\rangle=0$ for any $\psi \in \mathfrak{D}$ and $\varphi \in \operatorname{Ker}\left(A^{*}-z^{*}\right)$.

Note that by Lemma 4.9 two strongly continuous one-parameter groups commute,

$$
\begin{equation*}
\left[\mathrm{e}^{-\mathrm{i} t A}, \mathrm{e}^{-\mathrm{i} s B}\right]=0 \tag{5.5}
\end{equation*}
$$

if and only if the generators commute.
Clearly, for a physicist, one of the goals must be to understand the time evolution of a quantum mechanical system. We have seen that the time evolution is generated by a self-adjoint operator, the Hamiltonian, and is given by a linear first order differential equation, the Schrödinger equation. To understand the dynamics of such a first order differential equation, one must understand the spectrum of the generator. Some general tools for this endeavor will be provided in the following sections.

Problem 5.1. Let $\mathfrak{H}=L^{2}(0,2 \pi)$ and consider the one-parameter unitary group given by $U(t) f(x)=f(x-t \bmod 2 \pi)$. What is the generator of $U$ ?

### 5.2. The RAGE theorem

Now, let us discuss why the decomposition of the spectrum introduced in Section 3.3 is of physical relevance. Let $\|\varphi\|=\|\psi\|=1$. The vector $\langle\varphi, \psi\rangle \varphi$ is the projection of $\psi$ onto the (one-dimensional) subspace spanned by $\varphi$. Hence $|\langle\varphi, \psi\rangle|^{2}$ can be viewed as the part of $\psi$ which is in the state $\varphi$. The first question one might raise is, how does

$$
\begin{equation*}
|\langle\varphi, U(t) \psi\rangle|^{2}, \quad U(t)=\mathrm{e}^{-\mathrm{i} t A}, \tag{5.6}
\end{equation*}
$$

behave as $t \rightarrow \infty$ ? By the spectral theorem,

$$
\begin{equation*}
\hat{\mu}_{\varphi, \psi}(t)=\langle\varphi, U(t) \psi\rangle=\int_{\mathbb{R}} \mathrm{e}^{-\mathrm{i} t \lambda} d \mu_{\varphi, \psi}(\lambda) \tag{5.7}
\end{equation*}
$$

is the Fourier transform of the measure $\mu_{\varphi, \psi}$. Thus our question is answered by Wiener's theorem.

Theorem 5.4 (Wiener). Let $\mu$ be a finite complex Borel measure on $\mathbb{R}$ and let

$$
\begin{equation*}
\hat{\mu}(t)=\int_{\mathbb{R}} \mathrm{e}^{-\mathrm{i} t \lambda} d \mu(\lambda) \tag{5.8}
\end{equation*}
$$

be its Fourier transform. Then the Cesàro time average of $\hat{\mu}(t)$ has the limit

$$
\begin{equation*}
\lim _{T \rightarrow \infty} \frac{1}{T} \int_{0}^{T}|\hat{\mu}(t)|^{2} d t=\sum_{\lambda \in \mathbb{R}}|\mu(\{\lambda\})|^{2}, \tag{5.9}
\end{equation*}
$$

where the sum on the right-hand side is finite.

Proof. By Fubini we have

$$
\begin{aligned}
\frac{1}{T} \int_{0}^{T}|\hat{\mu}(t)|^{2} d t & =\frac{1}{T} \int_{0}^{T} \int_{\mathbb{R}} \int_{\mathbb{R}} \mathrm{e}^{-\mathrm{i}(x-y) t} d \mu(x) d \mu^{*}(y) d t \\
& =\int_{\mathbb{R}} \int_{\mathbb{R}}\left(\frac{1}{T} \int_{0}^{T} \mathrm{e}^{-\mathrm{i}(x-y) t} d t\right) d \mu(x) d \mu^{*}(y)
\end{aligned}
$$

The function in parentheses is bounded by one and converges pointwise to $\chi_{\{0\}}(x-y)$ as $T \rightarrow \infty$. Thus, by the dominated convergence theorem, the limit of the above expression is given by

$$
\int_{\mathbb{R}} \int_{\mathbb{R}} \chi_{\{0\}}(x-y) d \mu(x) d \mu^{*}(y)=\int_{\mathbb{R}} \mu(\{y\}) d \mu^{*}(y)=\sum_{y \in \mathbb{R}}|\mu(\{y\})|^{2}
$$

which finishes the proof.

To apply this result to our situation, observe that the subspaces $\mathfrak{H}_{a c}$, $\mathfrak{H}_{s c}$, and $\mathfrak{H}_{p p}$ are invariant with respect to time evolution since $P^{x x} U(t)=$ $\chi_{M_{x x}}(A) \exp (-\mathrm{i} t A)=\exp (-\mathrm{i} t A) \chi_{M_{x x}}(A)=U(t) P^{x x}, x x \in\{a c, s c, p p\}$. Moreover, if $\psi \in \mathfrak{H}_{x x}$, we have $P^{x x} \psi=\psi$, which shows $\langle\varphi, f(A) \psi\rangle=$ $\left\langle\varphi, P^{x x} f(A) \psi\right\rangle=\left\langle P^{x x} \varphi, f(A) \psi\right\rangle$ implying $d \mu_{\varphi, \psi}=d \mu_{P^{x x} \varphi, \psi}$. Thus if $\mu_{\psi}$ is $a c, s c$, or $p p$, so is $\mu_{\varphi, \psi}$ for every $\varphi \in \mathfrak{H}$.

That is, if $\psi \in \mathfrak{H}_{c}=\mathfrak{H}_{a c} \oplus \mathfrak{H}_{s c}$, then the Cesàro mean of $\langle\varphi, U(t) \psi\rangle$ tends to zero. In other words, the average of the probability of finding the system in any prescribed state tends to zero if we start in the continuous subspace $\mathfrak{H}_{c}$ of $A$.

If $\psi \in \mathfrak{H}_{a c}$, then $d \mu_{\varphi, \psi}$ is absolutely continuous with respect to Lebesgue measure and thus $\hat{\mu}_{\varphi, \psi}(t)$ is continuous and tends to zero as $|t| \rightarrow \infty$. In fact, this follows from the Riemann-Lebesgue lemma (see Lemma 7.6 below).

Now we want to draw some additional consequences from Wiener's theorem. This will eventually yield a dynamical characterization of the continuous and pure point spectrum due to Ruelle, Amrein, Gorgescu, and Enß. But first we need a few definitions.

An operator $K \in \mathfrak{L}(\mathfrak{H})$ is called a finite rank operator if its range is finite dimensional. The dimension

$$
\operatorname{rank}(K)=\operatorname{dim} \operatorname{Ran}(K)
$$

is called the rank of $K$. If $\left\{\psi_{j}\right\}_{j=1}^{n}$ is an orthonormal basis for $\operatorname{Ran}(K)$, we have

$$
\begin{equation*}
K \psi=\sum_{j=1}^{n}\left\langle\psi_{j}, K \psi\right\rangle \psi_{j}=\sum_{j=1}^{n}\left\langle\varphi_{j}, \psi\right\rangle \psi_{j} \tag{5.10}
\end{equation*}
$$

where $\varphi_{j}=K^{*} \psi_{j}$. The elements $\varphi_{j}$ are linearly independent since $\operatorname{Ran}(K)=$ $\operatorname{Ker}\left(K^{*}\right)^{\perp}$. Hence every finite rank operator is of the form (5.10). In addition, the adjoint of $K$ is also finite rank and is given by

$$
\begin{equation*}
K^{*} \psi=\sum_{j=1}^{n}\left\langle\psi_{j}, \psi\right\rangle \varphi_{j} . \tag{5.11}
\end{equation*}
$$

The closure of the set of all finite rank operators in $\mathfrak{L}(\mathfrak{H})$ is called the set of compact operators $\mathfrak{C}(\mathfrak{H})$. It is straightforward to verify (Problem 5.2)

Lemma 5.5. The set of all compact operators $\mathfrak{C}(\mathfrak{H})$ is a closed $*$-ideal in $\mathfrak{L}(\mathfrak{H})$.

There is also a weaker version of compactness which is useful for us. The operator $K$ is called relatively compact with respect to $A$ if

$$
\begin{equation*}
K R_{A}(z) \in \mathfrak{C}(\mathfrak{H}) \tag{5.12}
\end{equation*}
$$

for one $z \in \rho(A)$. By the first resolvent formula this then follows for all $z \in \rho(A)$. In particular we have $\mathfrak{D}(A) \subseteq \mathfrak{D}(K)$.

Now let us return to our original problem.
Theorem 5.6. Let $A$ be self-adjoint and suppose $K$ is relatively compact. Then

$$
\begin{equation*}
\lim _{T \rightarrow \infty} \frac{1}{T} \int_{0}^{T}\left\|K \mathrm{e}^{-\mathrm{i} t A} P^{c} \psi\right\|^{2} d t=0 \quad \text { and } \quad \lim _{t \rightarrow \infty}\left\|K \mathrm{e}^{-\mathrm{i} t A} P^{a c} \psi\right\|=0 \tag{5.13}
\end{equation*}
$$

for every $\psi \in \mathfrak{D}(A)$. If, in addition, $K$ is bounded, then the result holds for any $\psi \in \mathfrak{H}$.

Proof. Let $\psi \in \mathfrak{H}_{c}$, respectively, $\psi \in \mathfrak{H}_{a c}$, and drop the projectors. Then, if $K$ is a rank one operator (i.e., $K=\left\langle\varphi_{1},.\right\rangle \varphi_{2}$ ), the claim follows from Wiener's theorem, respectively, the Riemann-Lebesgue lemma. Hence it holds for any finite rank operator $K$.

If $K$ is compact, there is a sequence $K_{n}$ of finite rank operators such that $\left\|K-K_{n}\right\| \leq 1 / n$ and hence

$$
\left\|K \mathrm{e}^{-\mathrm{i} t A} \psi\right\| \leq\left\|K_{n} \mathrm{e}^{-\mathrm{i} t A} \psi\right\|+\frac{1}{n}\|\psi\|
$$

Thus the claim holds for any compact operator $K$.
If $\psi \in \mathfrak{D}(A)$, we can set $\psi=(A-\mathrm{i})^{-1} \varphi$, where $\varphi \in \mathfrak{H}_{c}$ if and only if $\psi \in \mathfrak{H}_{c}$ (since $\mathfrak{H}_{c}$ reduces $A$ ). Since $K(A+\mathrm{i})^{-1}$ is compact by assumption, the claim can be reduced to the previous situation. If $K$ is also bounded, we can find a sequence $\psi_{n} \in \mathfrak{D}(A)$ such that $\left\|\psi-\psi_{n}\right\| \leq 1 / n$ and hence

$$
\left\|K \mathrm{e}^{-\mathrm{i} t A} \psi\right\| \leq\left\|K \mathrm{e}^{-\mathrm{i} t A} \psi_{n}\right\|+\frac{1}{n}\|K\|,
$$

concluding the proof.

With the help of this result we can now prove an abstract version of the RAGE theorem.

Theorem 5.7 (RAGE). Let $A$ be self-adjoint. Suppose $K_{n} \in \mathfrak{L}(\mathfrak{H})$ is a sequence of relatively compact operators which converges strongly to the identity. Then

$$
\begin{align*}
\mathfrak{H}_{c} & =\left\{\psi \in \mathfrak{H} \left\lvert\, \lim _{n \rightarrow \infty} \lim _{T \rightarrow \infty} \frac{1}{T} \int_{0}^{T}\left\|K_{n} \mathrm{e}^{-\mathrm{i} t A} \psi\right\| d t=0\right.\right\}, \\
\mathfrak{H}_{p p} & =\left\{\psi \in \mathfrak{H} \mid \lim _{n \rightarrow \infty} \sup _{t \geq 0}\left\|\left(\mathbb{I}-K_{n}\right) \mathrm{e}^{-\mathrm{i} t A} \psi\right\|=0\right\} . \tag{5.14}
\end{align*}
$$

Proof. Abbreviate $\psi(t)=\exp (-\mathrm{i} t A) \psi$. We begin with the first equation.
Let $\psi \in \mathfrak{H}_{c}$. Then

$$
\frac{1}{T} \int_{0}^{T}\left\|K_{n} \psi(t)\right\| d t \leq\left(\frac{1}{T} \int_{0}^{T}\left\|K_{n} \psi(t)\right\|^{2} d t\right)^{1 / 2} \rightarrow 0
$$

by Cauchy-Schwarz and the previous theorem. Conversely, if $\psi \notin \mathfrak{H}_{c}$, we can write $\psi=\psi^{c}+\psi^{p p}$. By our previous estimate it suffices to show $\left\|K_{n} \psi^{p p}(t)\right\| \geq \varepsilon>0$ for $n$ large. In fact, we even claim

$$
\begin{equation*}
\lim _{n \rightarrow \infty} \sup _{t \geq 0}\left\|K_{n} \psi^{p p}(t)-\psi^{p p}(t)\right\|=0 \tag{5.15}
\end{equation*}
$$

By the spectral theorem, we can write $\psi^{p p}(t)=\sum_{j} \alpha_{j}(t) \psi_{j}$, where the $\psi_{j}$ are orthonormal eigenfunctions and $\alpha_{j}(t)=\exp \left(-\mathrm{i} t \lambda_{j}\right) \alpha_{j}$. Truncate this expansion after $N$ terms. Then this part converges uniformly to the desired limit by strong convergence of $K_{n}$. Moreover, by Lemma 1.14 we have $\left\|K_{n}\right\| \leq M$, and hence the error can be made arbitrarily small by choosing $N$ large.

Now let us turn to the second equation. If $\psi \in \mathfrak{H}_{p p}$, the claim follows by (5.15). Conversely, if $\psi \notin \mathfrak{H}_{p p}$, we can write $\psi=\psi^{c}+\psi^{p p}$ and by our previous estimate it suffices to show that $\left\|\left(\mathbb{I}-K_{n}\right) \psi^{c}(t)\right\|$ does not tend to 0 as $n \rightarrow \infty$. If it did, we would have

$$
\begin{aligned}
0 & =\lim _{T \rightarrow \infty} \frac{1}{T} \int_{0}^{T}\left\|\left(\mathbb{I}-K_{n}\right) \psi^{c}(t)\right\|^{2} d t \\
& \geq\left\|\psi^{c}(t)\right\|^{2}-\lim _{T \rightarrow \infty} \frac{1}{T} \int_{0}^{T}\left\|K_{n} \psi^{c}(t)\right\|^{2} d t=\left\|\psi^{c}(t)\right\|^{2},
\end{aligned}
$$

a contradiction.
In summary, regularity properties of spectral measures are related to the long time behavior of the corresponding quantum mechanical system. However, a more detailed investigation of this topic is beyond the scope of this manuscript. For a survey containing several recent results, see [28].

It is often convenient to treat the observables as time dependent rather than the states. We set

$$
\begin{equation*}
K(t)=\mathrm{e}^{\mathrm{i} t A} K \mathrm{e}^{-\mathrm{i} t A} \tag{5.16}
\end{equation*}
$$

and note

$$
\begin{equation*}
\langle\psi(t), K \psi(t)\rangle=\langle\psi, K(t) \psi\rangle, \quad \psi(t)=\mathrm{e}^{-\mathrm{i} t A} \psi . \tag{5.17}
\end{equation*}
$$

This point of view is often referred to as the Heisenberg picture in the physics literature. If $K$ is unbounded, we will assume $\mathfrak{D}(A) \subseteq \mathfrak{D}(K)$ such that the above equations make sense at least for $\psi \in \mathfrak{D}(A)$. The main interest is the behavior of $K(t)$ for large $t$. The strong limits are called asymptotic observables if they exist.

Theorem 5.8. Suppose $A$ is self-adjoint and $K$ is relatively compact. Then

$$
\begin{equation*}
\lim _{T \rightarrow \infty} \frac{1}{T} \int_{0}^{T} \mathrm{e}^{\mathrm{i} t A} K \mathrm{e}^{-\mathrm{i} t A} \psi d t=\sum_{\lambda \in \sigma_{p}(A)} P_{A}(\{\lambda\}) K P_{A}(\{\lambda\}) \psi, \quad \psi \in \mathfrak{D}(A) . \tag{5.18}
\end{equation*}
$$

If $K$ is in addition bounded, the result holds for any $\psi \in \mathfrak{H}$.
Proof. We will assume that $K$ is bounded. To obtain the general result, use the same trick as before and replace $K$ by $K R_{A}(z)$. Write $\psi=\psi^{c}+\psi^{p p}$. Then

$$
\lim _{T \rightarrow \infty} \frac{1}{T}\left\|\int_{0}^{T} K(t) \psi^{c} d t\right\| \leq \lim _{T \rightarrow \infty} \frac{1}{T} \int_{0}^{T}\left\|K(t) \psi^{c} d t\right\|=0
$$

by Theorem 5.6. As in the proof of the previous theorem we can write $\psi^{p p}=\sum_{j} \alpha_{j} \psi_{j}$ and hence

$$
\sum_{j} \alpha_{j} \frac{1}{T} \int_{0}^{T} K(t) \psi_{j} d t=\sum_{j} \alpha_{j}\left(\frac{1}{T} \int_{0}^{T} \mathrm{e}^{\mathrm{i} t\left(A-\lambda_{j}\right)} d t\right) K \psi_{j} .
$$

As in the proof of Wiener's theorem, we see that the operator in parentheses tends to $P_{A}\left(\left\{\lambda_{j}\right\}\right)$ strongly as $T \rightarrow \infty$. Since this operator is also bounded by 1 for all $T$, we can interchange the limit with the summation and the claim follows.

We also note the following corollary.
Corollary 5.9. Under the same assumptions as in the RAGE theorem we have

$$
\begin{equation*}
\lim _{n \rightarrow \infty} \lim _{T \rightarrow \infty} \frac{1}{T} \int_{0}^{T} \mathrm{e}^{\mathrm{i} t A} K_{n} \mathrm{e}^{-\mathrm{i} t A} \psi d t=P^{p p} \psi \tag{5.19}
\end{equation*}
$$

respectively,

$$
\begin{equation*}
\lim _{n \rightarrow \infty} \lim _{T \rightarrow \infty} \frac{1}{T} \int_{0}^{T} \mathrm{e}^{\mathrm{i} t A}\left(\mathbb{I}-K_{n}\right) \mathrm{e}^{-\mathrm{i} t A} \psi d t=P^{c} \psi \tag{5.20}
\end{equation*}
$$

Problem 5.2. Prove Lemma 5.5.

## Problem 5.3. Prove Corollary 5.9.

### 5.3. The Trotter product formula

In many situations the operator is of the form $A+B$, where $\mathrm{e}^{\mathrm{i} t A}$ and $\mathrm{e}^{\mathrm{i} t B}$ can be computed explicitly. Since $A$ and $B$ will not commute in general, we cannot obtain $\mathrm{e}^{\mathrm{it}(A+B)}$ from $\mathrm{e}^{\mathrm{i} t A} \mathrm{e}^{\mathrm{i} t B}$. However, we at least have
Theorem 5.10 (Trotter product formula). Suppose $A, B$, and $A+B$ are self-adjoint. Then

$$
\begin{equation*}
\mathrm{e}^{\mathrm{i} t(A+B)}=\underset{n \rightarrow \infty}{\mathrm{~s}-\lim _{\infty}}\left(\mathrm{e}^{\mathrm{i} \frac{t}{n} A} \mathrm{e}^{\mathrm{i} \frac{t}{n} B}\right)^{n} . \tag{5.21}
\end{equation*}
$$

Proof. First of all note that we have

$$
\begin{aligned}
& \left(\mathrm{e}^{\mathrm{i} \tau A} \mathrm{e}^{\mathrm{i} \tau B}\right)^{n}-\mathrm{e}^{\mathrm{i} t(A+B)} \\
& \quad=\sum_{j=0}^{n-1}\left(\mathrm{e}^{\mathrm{i} \tau A} \mathrm{e}^{\mathrm{i} \tau B}\right)^{n-1-j}\left(\mathrm{e}^{\mathrm{i} \tau A} \mathrm{e}^{\mathrm{i} \tau B}-\mathrm{e}^{\mathrm{i} \tau(A+B)}\right)\left(\mathrm{e}^{\mathrm{i} \tau(A+B)}\right)^{j},
\end{aligned}
$$

where $\tau=\frac{t}{n}$, and hence

$$
\left\|\left(\mathrm{e}^{\mathrm{i} \tau A} \mathrm{e}^{\mathrm{i} \tau B}\right)^{n}-\mathrm{e}^{\mathrm{i} t(A+B)} \psi\right\| \leq|t| \max _{|s| \leq|t|} F_{\tau}(s),
$$

where

$$
F_{\tau}(s)=\left\|\frac{1}{\tau}\left(\mathrm{e}^{\mathrm{i} \tau A} \mathrm{e}^{\mathrm{i} \tau B}-\mathrm{e}^{\mathrm{i} \tau(A+B)}\right) \mathrm{e}^{\mathrm{i} s(A+B)} \psi\right\| .
$$

Now for $\psi \in \mathfrak{D}(A+B)=\mathfrak{D}(A) \cap \mathfrak{D}(B)$ we have

$$
\frac{1}{\tau}\left(\mathrm{e}^{\mathrm{i} \tau A} \mathrm{e}^{\mathrm{i} \tau B}-\mathrm{e}^{\mathrm{i} \tau(A+B)}\right) \psi \rightarrow \mathrm{i} A \psi+\mathrm{i} B \psi-\mathrm{i}(A+B) \psi=0
$$

as $\tau \rightarrow 0$. So $\lim _{\tau \rightarrow 0} F_{\tau}(s)=0$ at least pointwise, but we need this uniformly with respect to $s \in[-|t|,|t|]$.

Pointwise convergence implies

$$
\left\|\frac{1}{\tau}\left(\mathrm{e}^{\mathrm{i} \tau A} \mathrm{e}^{\mathrm{i} \tau B}-\mathrm{e}^{\mathrm{i} \tau(A+B)}\right) \psi\right\| \leq C(\psi)
$$

and, since $\mathfrak{D}(A+B)$ is a Hilbert space when equipped with the graph norm $\|\psi\|_{\Gamma(A+B)}^{2}=\|\psi\|^{2}+\|(A+B) \psi\|^{2}$, we can invoke the uniform boundedness principle to obtain

$$
\left\|\frac{1}{\tau}\left(\mathrm{e}^{\mathrm{i} \tau A} \mathrm{e}^{\mathrm{i} \tau B}-\mathrm{e}^{\mathrm{i} \tau(A+B)}\right) \psi\right\| \leq C\|\psi\|_{\Gamma(A+B)} .
$$

Now

$$
\begin{aligned}
\left|F_{\tau}(s)-F_{\tau}(r)\right| & \leq\left\|\frac{1}{\tau}\left(\mathrm{e}^{\mathrm{i} \tau A} \mathrm{e}^{\mathrm{i} \tau B}-\mathrm{e}^{\mathrm{i} \tau(A+B)}\right)\left(\mathrm{e}^{\mathrm{i} s(A+B)}-\mathrm{e}^{\mathrm{i} r(A+B)}\right) \psi\right\| \\
& \leq C\left\|\left(\mathrm{e}^{\mathrm{i} s(A+B)}-\mathrm{e}^{\mathrm{i} r(A+B)}\right) \psi\right\|_{\Gamma(A+B)}
\end{aligned}
$$

shows that $F_{\tau}($.$) is uniformly continuous and the claim follows by a standard$ $\frac{\varepsilon}{2}$ argument.

If the operators are semi-bounded from below, the same proof shows
Theorem 5.11 (Trotter product formula). Suppose $A, B$, and $A+B$ are self-adjoint and semi-bounded from below. Then

$$
\begin{equation*}
\mathrm{e}^{-t(A+B)}=\underset{n \rightarrow \infty}{\mathrm{~s}-\lim _{n}}\left(\mathrm{e}^{-\frac{t}{n} A} \mathrm{e}^{-\frac{t}{n} B}\right)^{n}, \quad t \geq 0 \tag{5.22}
\end{equation*}
$$

Problem 5.4. Prove Theorem 5.11.

## Chapter 6

## Perturbation theory for self-adjoint operators

The Hamiltonian of a quantum mechanical system is usually the sum of the kinetic energy $H_{0}$ (free Schrödinger operator) plus an operator $V$ corresponding to the potential energy. Since $H_{0}$ is easy to investigate, one usually tries to consider $V$ as a perturbation of $H_{0}$. This will only work if $V$ is small with respect to $H_{0}$. Hence we study such perturbations of self-adjoint operators next.

### 6.1. Relatively bounded operators and the Kato-Rellich theorem

An operator $B$ is called $A$ bounded or relatively bounded with respect to $A$ if $\mathfrak{D}(A) \subseteq \mathfrak{D}(B)$ and if there are constants $a, b \geq 0$ such that

$$
\begin{equation*}
\|B \psi\| \leq a\|A \psi\|+b\|\psi\|, \quad \psi \in \mathfrak{D}(A) \tag{6.1}
\end{equation*}
$$

The infimum of all constants $a$ for which a corresponding $b$ exists such that (6.1) holds is called the $A$-bound of $B$.

The triangle inequality implies
Lemma 6.1. Suppose $B_{j}, j=1,2$, are $A$ bounded with respective $A$-bounds $a_{i}, i=1,2$. Then $\alpha_{1} B_{1}+\alpha_{2} B_{2}$ is also $A$ bounded with $A$-bound less than $\left|\alpha_{1}\right| a_{1}+\left|\alpha_{2}\right| a_{2}$. In particular, the set of all $A$ bounded operators forms a linear space.

There are also the following equivalent characterizations:

Lemma 6.2. Suppose $A$ is closed and $B$ is closable. Then the following are equivalent:
(i) $B$ is $A$ bounded.
(ii) $\mathfrak{D}(A) \subseteq \mathfrak{D}(B)$.
(iii) $B R_{A}(z)$ is bounded for one (and hence for all) $z \in \rho(A)$.

Moreover, the $A$-bound of $B$ is no larger than $\inf _{z \in \rho(A)}\left\|B R_{A}(z)\right\|$.
Proof. (i) $\Rightarrow$ (ii) is true by definition. (ii) $\Rightarrow$ (iii) since $B R_{A}(z)$ is a closed (Problem 2.9) operator defined on all of $\mathfrak{H}$ and hence bounded by the closed graph theorem (Theorem 2.8). To see (iii) $\Rightarrow$ (i), let $\psi \in \mathfrak{D}(A)$. Then

$$
\|B \psi\|=\left\|B R_{A}(z)(A-z) \psi\right\| \leq a\|(A-z) \psi\| \leq a\|A \psi\|+(a|z|)\|\psi\|,
$$

where $a=\left\|B R_{A}(z)\right\|$. Finally, note that if $B R_{A}(z)$ is bounded for one $z \in \rho(A)$, it is bounded for all $z \in \rho(A)$ by the first resolvent formula.

Example. Let $A$ be the self-adjoint operator $A=-\frac{d^{2}}{d x^{2}}, \mathfrak{D}(A)=\{f \in$ $\left.H^{2}[0,1] \mid f(0)=f(1)=0\right\}$ in the Hilbert space $L^{2}(0,1)$. If we want to add a potential represented by a multiplication operator with a real-valued (measurable) function $q$, then $q$ will be relatively bounded if $q \in L^{2}(0,1)$ : Indeed, since all functions in $\mathfrak{D}(A)$ are continuous on $[0,1]$ and hence bounded, we clearly have $\mathfrak{D}(A) \subset \mathfrak{D}(q)$ in this case.

We are mainly interested in the situation where $A$ is self-adjoint and $B$ is symmetric. Hence we will restrict our attention to this case.

Lemma 6.3. Suppose $A$ is self-adjoint and $B$ relatively bounded. The $A$ bound of $B$ is given by

$$
\begin{equation*}
\lim _{\lambda \rightarrow \infty}\left\|B R_{A}( \pm \mathrm{i} \lambda)\right\| . \tag{6.2}
\end{equation*}
$$

If $A$ is bounded from below, we can also replace $\pm \mathrm{i} \lambda$ by $-\lambda$.
Proof. Let $\varphi=R_{A}( \pm \mathrm{i} \lambda) \psi, \lambda>0$, and let $a_{\infty}$ be the $A$-bound of $B$. Then (use the spectral theorem to estimate the norms)

$$
\left\|B R_{A}( \pm \mathrm{i} \lambda) \psi\right\| \leq a\left\|A R_{A}( \pm \mathrm{i} \lambda) \psi\right\|+b\left\|R_{A}( \pm \mathrm{i} \lambda) \psi\right\| \leq\left(a+\frac{b}{\lambda}\right)\|\psi\| .
$$

Hence $\lim \sup _{\lambda}\left\|B R_{A}( \pm \mathrm{i} \lambda)\right\| \leq a_{\infty}$ which, together with the inequality $a_{\infty} \leq$ $\inf _{\lambda}\left\|B R_{A}( \pm \mathrm{i} \lambda)\right\|$ from the previous lemma, proves the claim.

The case where $A$ is bounded from below is similar, using

$$
\left\|B R_{A}(-\lambda) \psi\right\| \leq\left(a \max \left(1, \frac{|\gamma|}{\lambda+\gamma}\right)+\frac{b}{\lambda+\gamma}\right)\|\psi\|,
$$

for $-\lambda<\gamma$.
Now we will show the basic perturbation result due to Kato and Rellich.

Theorem 6.4 (Kato-Rellich). Suppose $A$ is (essentially) self-adjoint and $B$ is symmetric with $A$-bound less than one. Then $A+B, \mathfrak{D}(A+B)=$ $\mathfrak{D}(\underline{A})$, is (essentially) self-adjoint. If $A$ is essentially self-adjoint, we have $\mathfrak{D}(\bar{A}) \subseteq \mathfrak{D}(\bar{B})$ and $\bar{A}+\bar{B}=\overline{A+B}$.

If $A$ is bounded from below by $\gamma$, then $A+B$ is bounded from below by

$$
\begin{equation*}
\gamma-\max \left(a|\gamma|+b, \frac{b}{a-1}\right) \tag{6.3}
\end{equation*}
$$

Proof. Since $\mathfrak{D}(\bar{A}) \subseteq \mathfrak{D}(\bar{B})$ and $\mathfrak{D}(\bar{A}) \subseteq \mathfrak{D}(\overline{A+B})$ by (6.1), we can assume that $A$ is closed (i.e., self-adjoint). It suffices to show that $\operatorname{Ran}(A+B \pm \mathrm{i} \lambda)=$ $\mathfrak{H}$. By the above lemma we can find a $\lambda>0$ such that $\left\|B R_{A}( \pm \mathrm{i} \lambda)\right\|<1$. Hence $-1 \in \rho\left(B R_{A}( \pm \mathrm{i} \lambda)\right)$ and thus $\mathbb{I}+B R_{A}( \pm \mathrm{i} \lambda)$ is onto. Thus

$$
(A+B \pm \mathrm{i} \lambda)=\left(\mathbb{I}+B R_{A}( \pm \mathrm{i} \lambda)\right)(A \pm \mathrm{i} \lambda)
$$

is onto and the proof of the first part is complete.
If $A$ is bounded from below, we can replace $\pm \mathrm{i} \lambda$ by $-\lambda$ and the above equation shows that $R_{A+B}$ exists for $\lambda$ sufficiently large. By the proof of the previous lemma we can choose $-\lambda<\min (\gamma, b /(a-1))$.

Example. In our previous example we have seen that $q \in L^{2}(0,1)$ is relatively bounded by checking $\mathfrak{D}(A) \subset \mathfrak{D}(q)$. However, working a bit harder (Problem 6.2), one can even show that the relative bound is 0 and hence $A+q$ is self-adjoint by the Kato-Rellich theorem.

Finally, let us show that there is also a connection between the resolvents.
Lemma 6.5. Suppose $A$ and $B$ are closed and $\mathfrak{D}(A) \subseteq \mathfrak{D}(B)$. Then we have the second resolvent formula

$$
\begin{equation*}
R_{A+B}(z)-R_{A}(z)=-R_{A}(z) B R_{A+B}(z)=-R_{A+B}(z) B R_{A}(z) \tag{6.4}
\end{equation*}
$$

for $z \in \rho(A) \cap \rho(A+B)$.
Proof. We compute

$$
R_{A+B}(z)+R_{A}(z) B R_{A+B}(z)=R_{A}(z)(A+B-z) R_{A+B}(z)=R_{A}(z)
$$

The second identity is similar.
Problem 6.1. Show that (6.1) implies

$$
\|B \psi\|^{2} \leq \tilde{a}^{2}\|A \psi\|^{2}+\tilde{b}^{2}\|\psi\|^{2}
$$

with $\tilde{a}=a\left(1+\varepsilon^{2}\right)$ and $\tilde{b}=b\left(1+\varepsilon^{-2}\right)$ for any $\varepsilon>0$. Conversely, show that this inequality implies (6.1) with $a=\tilde{a}$ and $b=\tilde{b}$.

Problem 6.2. Let $A$ be the self-adjoint operator $A=-\frac{d^{2}}{d x^{2}}, \mathfrak{D}(A)=\{f \in$ $\left.H^{2}[0,1] \mid f(0)=f(1)=0\right\}$ in the Hilbert space $L^{2}(0,1)$ and $q \in L^{2}(0,1)$.

Show that for every $f \in \mathfrak{D}(A)$ we have

$$
\|f\|_{\infty}^{2} \leq \frac{\varepsilon}{2}\left\|f^{\prime \prime}\right\|^{2}+\frac{1}{2 \varepsilon}\|f\|^{2}
$$

for any $\varepsilon>0$. Conclude that the relative bound of $q$ with respect to $A$ is zero. (Hint: $|f(x)|^{2} \leq\left|\int_{0}^{1} f^{\prime}(t) d t\right|^{2} \leq \int_{0}^{1}\left|f^{\prime}(t)\right|^{2} d t=-\int_{0}^{1} f(t)^{*} f^{\prime \prime}(t) d t$.)
Problem 6.3. Let $A$ be as in the previous example. Show that $q$ is relatively bounded if and only if $x(1-x) q(x) \in L^{2}(0,1)$.
Problem 6.4. Compute the resolvent of $A+\alpha\langle\psi,.\rangle \psi$. (Hint: Show

$$
(\mathbb{I}+\alpha\langle\varphi, .\rangle \psi)^{-1}=\mathbb{I}-\frac{\alpha}{1+\alpha\langle\varphi, \psi\rangle}\langle\varphi, .\rangle \psi
$$

and use the second resolvent formula.)

### 6.2. More on compact operators

Recall from Section 5.2 that we have introduced the set of compact operators $\mathfrak{C}(\mathfrak{H})$ as the closure of the set of all finite rank operators in $\mathfrak{L}(\mathfrak{H})$. Before we can proceed, we need to establish some further results for such operators. We begin by investigating the spectrum of self-adjoint compact operators and show that the spectral theorem takes a particularly simple form in this case.

Theorem 6.6 (Spectral theorem for compact operators). Suppose the operator $K$ is self-adjoint and compact. Then the spectrum of $K$ consists of an at most countable number of eigenvalues which can only cluster at 0. Moreover, the eigenspace to each nonzero eigenvalue is finite dimensional.

In addition, we have

$$
\begin{equation*}
K=\sum_{\lambda \in \sigma(K)} \lambda P_{K}(\{\lambda\}) . \tag{6.5}
\end{equation*}
$$

Proof. It suffices to show $\operatorname{rank}\left(P_{K}((\lambda-\varepsilon, \lambda+\varepsilon))\right)<\infty$ for $0<\varepsilon<|\lambda|$. Let $K_{n}$ be a sequence of finite rank operators such that $\left\|K-K_{n}\right\| \leq 1 / n$. If $\operatorname{Ran} P_{K}((\lambda-\varepsilon, \lambda+\varepsilon))$ is infinite dimensional, we can find a vector $\psi_{n}$ in this range such that $\left\|\psi_{n}\right\|=1$ and $K_{n} \psi_{n}=0$. But this yields a contradiction since

$$
\frac{1}{n} \geq\left|\left\langle\psi_{n},\left(K-K_{n}\right) \psi_{n}\right\rangle\right|=\left|\left\langle\psi_{n}, K \psi_{n}\right\rangle\right| \geq|\lambda|-\varepsilon>0
$$

by (4.2).
As a consequence we obtain the canonical form of a general compact operator.

Theorem 6.7 (Canonical form of compact operators). Let $K$ be compact. There exist orthonormal sets $\left\{\hat{\phi}_{j}\right\},\left\{\phi_{j}\right\}$ and positive numbers $s_{j}=s_{j}(K)$ such that

$$
\begin{equation*}
K=\sum_{j} s_{j}\left\langle\phi_{j}, .\right\rangle \hat{\phi}_{j}, \quad K^{*}=\sum_{j} s_{j}\left\langle\hat{\phi}_{j}, .\right\rangle \phi_{j} . \tag{6.6}
\end{equation*}
$$

Note $K \phi_{j}=s_{j} \hat{\phi}_{j}$ and $K^{*} \hat{\phi}_{j}=s_{j} \phi_{j}$, and hence $K^{*} K \phi_{j}=s_{j}^{2} \phi_{j}$ and $K K^{*} \hat{\phi}_{j}=$ $s_{j}^{2} \hat{\phi}_{j}$.

The numbers $s_{j}(K)^{2}>0$ are the nonzero eigenvalues of $K K^{*}$, respectively, $K^{*} K$ (counted with multiplicity) and $s_{j}(K)=s_{j}\left(K^{*}\right)=s_{j}$ are called singular values of $K$. There are either finitely many singular values (if $K$ is finite rank) or they converge to zero.

Proof. By Lemma 5.5, $K^{*} K$ is compact and hence Theorem 6.6 applies. Let $\left\{\phi_{j}\right\}$ be an orthonormal basis of eigenvectors for $P_{K^{*} K}((0, \infty)) \mathfrak{H}$ and let $s_{j}^{2}$ be the eigenvalue corresponding to $\phi_{j}$. Then, for any $\psi \in \mathfrak{H}$ we can write

$$
\psi=\sum_{j}\left\langle\phi_{j}, \psi\right\rangle \phi_{j}+\tilde{\psi}
$$

with $\tilde{\psi} \in \operatorname{Ker}\left(K^{*} K\right)=\operatorname{Ker}(K)$. Then

$$
K \psi=\sum_{j} s_{j}\left\langle\phi_{j}, \psi\right\rangle \hat{\phi}_{j},
$$

where $\hat{\phi}_{j}=s_{j}^{-1} K \phi_{j}$, since $\|K \tilde{\psi}\|^{2}=\left\langle\tilde{\psi}, K^{*} K \tilde{\psi}\right\rangle=0 . \quad$ By $\left\langle\hat{\phi}_{j}, \hat{\phi}_{k}\right\rangle=$ $\left(s_{j} s_{k}\right)^{-1}\left\langle K \phi_{j}, K \phi_{k}\right\rangle=\left(s_{j} s_{k}\right)^{-1}\left\langle K^{*} K \phi_{j}, \phi_{k}\right\rangle=s_{j} s_{k}^{-1}\left\langle\phi_{j}, \phi_{k}\right\rangle$ we see that the $\left\{\hat{\phi}_{j}\right\}$ are orthonormal and the formula for $K^{*}$ follows by taking the adjoint of the formula for $K$ (Problem 6.5).

If $K$ is self-adjoint, then $\phi_{j}=\sigma_{j} \hat{\phi}_{j}, \sigma_{j}^{2}=1$ are the eigenvectors of $K$ and $\sigma_{j} s_{j}$ are the corresponding eigenvalues.

Moreover, note that we have

$$
\begin{equation*}
\|K\|=\max _{j} s_{j}(K) . \tag{6.7}
\end{equation*}
$$

Finally, let me remark that there are a number of other equivalent definitions for compact operators.

Lemma 6.8. For $K \in \mathfrak{L}(\mathfrak{H})$ the following statements are equivalent:
(i) $K$ is compact.
(i') $K^{*}$ is compact.
(ii) $A_{n} \in \mathfrak{L}(\mathfrak{H})$ and $A_{n} \xrightarrow{s} A$ strongly implies $A_{n} K \rightarrow A K$.
(iii) $\psi_{n} \rightharpoonup \psi$ weakly implies $K \psi_{n} \rightarrow K \psi$ in norm.
(iv) $\psi_{n}$ bounded implies that $K \psi_{n}$ has a (norm) convergent subsequence.

Proof. (i) $\Leftrightarrow$ (i'). This is immediate from Theorem 6.7.
(i) $\Rightarrow$ (ii). Translating $A_{n} \rightarrow A_{n}-A$, it is no restriction to assume $A=0$. Since $\left\|A_{n}\right\| \leq M$, it suffices to consider the case where $K$ is finite rank. Then (by (6.6))

$$
\left\|A_{n} K\right\|^{2}=\sup _{\|\psi\|=1} \sum_{j=1}^{N} s_{j}\left|\left\langle\phi_{j}, \psi\right\rangle\right|^{2}\left\|A_{n} \hat{\phi}_{j}\right\|^{2} \leq \sum_{j=1}^{N} s_{j}\left\|A_{n} \hat{\phi}_{j}\right\|^{2} \rightarrow 0 .
$$

(ii) $\Rightarrow$ (iii). Again, replace $\psi_{n} \rightarrow \psi_{n}-\psi$ and assume $\psi=0$. Choose $A_{n}=\left\langle\psi_{n},.\right\rangle \varphi,\|\varphi\|=1$. Then $\left\|K \psi_{n}\right\|=\left\|A_{n} K^{*}\right\| \rightarrow 0$.
(iii) $\Rightarrow$ (iv). If $\psi_{n}$ is bounded, it has a weakly convergent subsequence by Lemma 1.13. Now apply (iii) to this subsequence.
(iv) $\Rightarrow$ (i). Let $\varphi_{j}$ be an orthonormal basis and set

$$
K_{n}=\sum_{j=1}^{n}\left\langle\varphi_{j}, .\right\rangle K \varphi_{j} .
$$

Then

$$
\gamma_{n}=\left\|K-K_{n}\right\|=\sup _{\psi \in \operatorname{span}\left\{\varphi_{j}\right\}_{j=n}^{\infty},\|\psi\|=1}\|K \psi\|
$$

is a decreasing sequence tending to a limit $\varepsilon \geq 0$. Moreover, we can find a sequence of unit vectors $\psi_{n} \in \operatorname{span}\left\{\varphi_{j}\right\}_{j=n}^{\infty}$ for which $\left\|K \psi_{n}\right\| \geq \varepsilon$. By assumption, $K \psi_{n}$ has a convergent subsequence which, since $\psi_{n}$ converges weakly to 0 , converges to 0 . Hence $\varepsilon$ must be 0 and we are done.

The last condition explains the name compact. Moreover, note that one cannot replace $A_{n} K \rightarrow A K$ by $K A_{n} \rightarrow K A$ in (ii) unless one additionally requires $A_{n}$ to be normal (then this follows by taking adjoints - recall that only for normal operators is taking adjoints continuous with respect to strong convergence). Without the requirement that $A_{n}$ be normal, the claim is wrong as the following example shows.
Example. Let $\mathfrak{H}=\ell^{2}(\mathbb{N})$ and let $A_{n}$ be the operator which shifts each sequence $n$ places to the left and let $K=\left\langle\delta_{1},.\right\rangle \delta_{1}$, where $\delta_{1}=(1,0, \ldots)$. Then s-lim $A_{n}=0$ but $\left\|K A_{n}\right\|=1$.

Problem 6.5. Deduce the formula for $K^{*}$ from the one for $K$ in (6.6).
Problem 6.6. Show that it suffices to check conditions (iii) and (iv) from Lemma 6.8 on a dense subset.

### 6.3. Hilbert-Schmidt and trace class operators

Among the compact operators two special classes are of particular importance. The first ones are integral operators

$$
\begin{equation*}
K \psi(x)=\int_{M} K(x, y) \psi(y) d \mu(y), \quad \psi \in L^{2}(M, d \mu) \tag{6.8}
\end{equation*}
$$

where $K(x, y) \in L^{2}(M \times M, d \mu \otimes d \mu)$. Such an operator is called a HilbertSchmidt operator. Using Cauchy-Schwarz,

$$
\begin{align*}
& \int_{M}|K \psi(x)|^{2} d \mu(x)=\int_{M}\left|\int_{M}\right| K(x, y) \psi(y)|d \mu(y)|^{2} d \mu(x) \\
& \leq \int_{M}\left(\int_{M}|K(x, y)|^{2} d \mu(y)\right)\left(\int_{M}|\psi(y)|^{2} d \mu(y)\right) d \mu(x) \\
& \quad=\left(\int_{M} \int_{M}|K(x, y)|^{2} d \mu(y) d \mu(x)\right)\left(\int_{M}|\psi(y)|^{2} d \mu(y)\right), \tag{6.9}
\end{align*}
$$

we see that $K$ is bounded. Next, pick an orthonormal basis $\varphi_{j}(x)$ for $L^{2}(M, d \mu)$. Then, by Lemma 1.10, $\varphi_{i}(x) \varphi_{j}(y)$ is an orthonormal basis for $L^{2}(M \times M, d \mu \otimes d \mu)$ and

$$
\begin{equation*}
K(x, y)=\sum_{i, j} c_{i, j} \varphi_{i}(x) \varphi_{j}(y), \quad c_{i, j}=\left\langle\varphi_{i}, K \varphi_{j}^{*}\right\rangle, \tag{6.10}
\end{equation*}
$$

where

$$
\begin{equation*}
\sum_{i, j}\left|c_{i, j}\right|^{2}=\int_{M} \int_{M}|K(x, y)|^{2} d \mu(y) d \mu(x)<\infty \tag{6.11}
\end{equation*}
$$

In particular,

$$
\begin{equation*}
K \psi(x)=\sum_{i, j} c_{i, j}\left\langle\varphi_{j}^{*}, \psi\right\rangle \varphi_{i}(x) \tag{6.12}
\end{equation*}
$$

shows that $K$ can be approximated by finite rank operators (take finitely many terms in the sum) and is hence compact.

Using (6.6), we can also give a different characterization of HilbertSchmidt operators.

Lemma 6.9. If $\mathfrak{H}=L^{2}(M, d \mu)$, then a compact operator $K$ is HilbertSchmidt if and only if $\sum_{j} s_{j}(K)^{2}<\infty$ and

$$
\begin{equation*}
\sum_{j} s_{j}(K)^{2}=\int_{M} \int_{M}|K(x, y)|^{2} d \mu(x) d \mu(y) \tag{6.13}
\end{equation*}
$$

in this case.

Proof. If $K$ is compact, we can define approximating finite rank operators $K_{n}$ by considering only finitely many terms in (6.6):

$$
K_{n}=\sum_{j=1}^{n} s_{j}\left\langle\phi_{j}, .\right\rangle \hat{\phi}_{j} .
$$

Then $K_{n}$ has the kernel $K_{n}(x, y)=\sum_{j=1}^{n} s_{j} \phi_{j}(y)^{*} \hat{\phi}_{j}(x)$ and

$$
\int_{M} \int_{M}\left|K_{n}(x, y)\right|^{2} d \mu(x) d \mu(y)=\sum_{j=1}^{n} s_{j}(K)^{2} .
$$

Now if one side converges, so does the other and, in particular, (6.13) holds in this case.

Hence we will call a compact operator Hilbert-Schmidt if its singular values satisfy

$$
\begin{equation*}
\sum_{j} s_{j}(K)^{2}<\infty . \tag{6.14}
\end{equation*}
$$

By our lemma this coincides with our previous definition if $\mathfrak{H}=L^{2}(M, d \mu)$.
Since every Hilbert space is isomorphic to some $L^{2}(M, d \mu)$, we see that the Hilbert-Schmidt operators together with the norm

$$
\begin{equation*}
\|K\|_{2}=\left(\sum_{j} s_{j}(K)^{2}\right)^{1 / 2} \tag{6.15}
\end{equation*}
$$

form a Hilbert space (isomorphic to $L^{2}(M \times M, d \mu \otimes d \mu)$ ). Note that $\|K\|_{2}=$ $\left\|K^{*}\right\|_{2}$ (since $s_{j}(K)=s_{j}\left(K^{*}\right)$ ). There is another useful characterization for identifying Hilbert-Schmidt operators:

Lemma 6.10. A compact operator $K$ is Hilbert-Schmidt if and only if

$$
\begin{equation*}
\sum_{n}\left\|K \psi_{n}\right\|^{2}<\infty \tag{6.16}
\end{equation*}
$$

for some orthonormal basis and

$$
\begin{equation*}
\sum_{n}\left\|K \psi_{n}\right\|^{2}=\|K\|_{2}^{2} \tag{6.17}
\end{equation*}
$$

for any orthonormal basis in this case.
Proof. This follows from

$$
\begin{aligned}
\sum_{n}\left\|K \psi_{n}\right\|^{2} & =\sum_{n, j}\left|\left\langle\hat{\phi}_{j}, K \psi_{n}\right\rangle\right|^{2}=\sum_{n, j}\left|\left\langle K^{*} \hat{\phi}_{j}, \psi_{n}\right\rangle\right|^{2} \\
& =\sum_{n}\left\|K^{*} \hat{\phi}_{n}\right\|^{2}=\sum_{j} s_{j}(K)^{2} .
\end{aligned}
$$

Corollary 6.11. The set of Hilbert-Schmidt operators forms a*-ideal in $\mathfrak{L}(\mathfrak{H})$ and

$$
\begin{equation*}
\|K A\|_{2} \leq\|A\|\|K\|_{2}, \quad \text { respectively, } \quad\|A K\|_{2} \leq\|A\|\|K\|_{2} . \tag{6.18}
\end{equation*}
$$

Proof. Let $K$ be Hilbert-Schmidt and $A$ bounded. Then $A K$ is compact and

$$
\|A K\|_{2}^{2}=\sum_{n}\left\|A K \psi_{n}\right\|^{2} \leq\|A\|^{2} \sum_{n}\left\|K \psi_{n}\right\|^{2}=\|A\|^{2}\|K\|_{2}^{2}
$$

For $K A$ just consider adjoints.

This approach can be generalized by defining

$$
\begin{equation*}
\|K\|_{p}=\left(\sum_{j} s_{j}(K)^{p}\right)^{1 / p} \tag{6.19}
\end{equation*}
$$

plus corresponding spaces

$$
\begin{equation*}
\mathcal{J}_{p}(\mathfrak{H})=\left\{K \in \mathfrak{C}(\mathfrak{H})\|K\|_{p}<\infty\right\}, \tag{6.20}
\end{equation*}
$$

which are known as Schatten $p$-classes. Note that by (6.7)

$$
\begin{equation*}
\|K\| \leq\|K\|_{p} \tag{6.21}
\end{equation*}
$$

and that by $s_{j}(K)=s_{j}\left(K^{*}\right)$ we have

$$
\begin{equation*}
\|K\|_{p}=\left\|K^{*}\right\|_{p} \tag{6.22}
\end{equation*}
$$

Lemma 6.12. The spaces $\mathcal{J}_{p}(\mathfrak{H})$ together with the norm $\|\cdot\|_{p}$ are Banach spaces. Moreover,

$$
\begin{equation*}
\|K\|_{p}=\sup \left\{\left(\sum_{j}\left|\left\langle\psi_{j}, K \varphi_{j}\right\rangle\right|^{p}\right)^{1 / p} \mid\left\{\psi_{j}\right\},\left\{\varphi_{j}\right\} \text { ONS }\right\} \tag{6.23}
\end{equation*}
$$

where the sup is taken over all orthonormal sets.
Proof. The hard part is to prove (6.23): Choose $q$ such that $\frac{1}{p}+\frac{1}{q}=1$ and use Hölder's inequality to obtain $\left(s_{j}|\ldots|^{2}=\left(s_{j}^{p}|\ldots|^{2}\right)^{1 / p}|\ldots|^{2 / q}\right)$

$$
\begin{aligned}
\sum_{j} s_{j}\left|\left\langle\varphi_{n}, \phi_{j}\right\rangle\right|^{2} & \leq\left(\sum_{j} s_{j}^{p}\left|\left\langle\varphi_{n}, \phi_{j}\right\rangle\right|^{2}\right)^{1 / p}\left(\sum_{j}\left|\left\langle\varphi_{n}, \phi_{j}\right\rangle\right|^{2}\right)^{1 / q} \\
& \leq\left(\sum_{j} s_{j}^{p}\left|\left\langle\varphi_{n}, \phi_{j}\right\rangle\right|^{2}\right)^{1 / p} .
\end{aligned}
$$

Clearly the analogous equation holds for $\hat{\phi}_{j}, \psi_{n}$. Now using Cauchy-Schwarz, we have

$$
\begin{aligned}
\left|\left\langle\psi_{n}, K \varphi_{n}\right\rangle\right|^{p} & =\left|\sum_{j} s_{j}^{1 / 2}\left\langle\varphi_{n}, \phi_{j}\right\rangle s_{j}^{1 / 2}\left\langle\hat{\phi}_{j}, \psi_{n}\right\rangle\right|^{p} \\
& \leq\left(\sum_{j} s_{j}^{p}\left|\left\langle\varphi_{n}, \phi_{j}\right\rangle\right|^{2}\right)^{1 / 2}\left(\sum_{j} s_{j}^{p}\left|\left\langle\psi_{n}, \hat{\phi}_{j}\right\rangle\right|^{2}\right)^{1 / 2}
\end{aligned}
$$

Summing over $n$, a second appeal to Cauchy-Schwarz and interchanging the order of summation finally gives

$$
\begin{aligned}
\sum_{n}\left|\left\langle\psi_{n}, K \varphi_{n}\right\rangle\right|^{p} & \leq\left(\sum_{n, j} s_{j}^{p}\left|\left\langle\varphi_{n}, \phi_{j}\right\rangle\right|^{2}\right)^{1 / 2}\left(\sum_{n, j} s_{j}^{p}\left|\left\langle\psi_{n}, \hat{\phi}_{j}\right\rangle\right|^{2}\right)^{1 / 2} \\
& \leq\left(\sum_{j} s_{j}^{p}\right)^{1 / 2}\left(\sum_{j} s_{j}^{p}\right)^{1 / 2}=\sum_{j} s_{j}^{p} .
\end{aligned}
$$

Since equality is attained for $\varphi_{n}=\phi_{n}$ and $\psi_{n}=\hat{\phi}_{n}$, equation (6.23) holds.
Now the rest is straightforward. From

$$
\begin{aligned}
& \left(\sum_{j}\left|\left\langle\psi_{j},\left(K_{1}+K_{2}\right) \varphi_{j}\right\rangle\right|^{p}\right)^{1 / p} \\
& \quad \leq\left(\sum_{j}\left|\left\langle\psi_{j}, K_{1} \varphi_{j}\right\rangle\right|^{p}\right)^{1 / p}+\left(\sum_{j}\left|\left\langle\psi_{j}, K_{2} \varphi_{j}\right\rangle\right|^{p}\right)^{1 / p} \\
& \quad \leq\left\|K_{1}\right\|_{p}+\left\|K_{2}\right\|_{p}
\end{aligned}
$$

we infer that $\mathcal{J}_{p}(\mathfrak{H})$ is a vector space and the triangle inequality. The other requirements for a norm are obvious and it remains to check completeness. If $K_{n}$ is a Cauchy sequence with respect to $\|\cdot\|_{p}$, it is also a Cauchy sequence with respect to $\|\|.\left(\|K\| \leq\|K\|_{p}\right)$. Since $\mathfrak{C}(\mathfrak{H})$ is closed, there is a compact $K$ with $\left\|K-K_{n}\right\| \rightarrow 0$ and by $\left\|K_{n}\right\|_{p} \leq C$ we have

$$
\left(\sum_{j}\left|\left\langle\psi_{j}, K \varphi_{j}\right\rangle\right|^{p}\right)^{1 / p} \leq C
$$

for any finite ONS. Since the right-hand side is independent of the ONS (and in particular on the number of vectors), $K$ is in $\mathcal{J}_{p}(\mathfrak{H})$.

The two most important cases are $p=1$ and $p=2: \mathcal{J}_{2}(\mathfrak{H})$ is the space of Hilbert-Schmidt operators investigated in the previous section and $\mathcal{J}_{1}(\mathfrak{H})$ is the space of trace class operators. Since Hilbert-Schmidt operators are easy to identify, it is important to relate $\mathcal{J}_{1}(\mathfrak{H})$ with $\mathcal{J}_{2}(\mathfrak{H})$ :

Lemma 6.13. An operator is trace class if and only if it can be written as the product of two Hilbert-Schmidt operators, $K=K_{1} K_{2}$, and in this case
we have

$$
\begin{equation*}
\|K\|_{1} \leq\left\|K_{1}\right\|_{2}\left\|K_{2}\right\|_{2} . \tag{6.24}
\end{equation*}
$$

Proof. By Cauchy-Schwarz we have

$$
\begin{aligned}
\sum_{n}\left|\left\langle\varphi_{n}, K \psi_{n}\right\rangle\right| & =\sum_{n}\left|\left\langle K_{1}^{*} \varphi_{n}, K_{2} \psi_{n}\right\rangle\right| \leq\left(\sum_{n}\left\|K_{1}^{*} \varphi_{n}\right\|^{2} \sum_{n}\left\|K_{2} \psi_{n}\right\|^{2}\right)^{1 / 2} \\
& =\left\|K_{1}\right\|_{2}\left\|K_{2}\right\|_{2}
\end{aligned}
$$

and hence $K=K_{1} K_{2}$ is trace class if both $K_{1}$ and $K_{2}$ are Hilbert-Schmidt operators. To see the converse, let $K$ be given by (6.6) and choose $K_{1}=$ $\sum_{j} \sqrt{s_{j}(K)}\left\langle\phi_{j},.\right\rangle \hat{\phi}_{j}$, respectively, $K_{2}=\sum_{j} \sqrt{s_{j}(K)}\left\langle\phi_{j},.\right\rangle \phi_{j}$.

Corollary 6.14. The set of trace class operators forms a*-ideal in $\mathfrak{L}(\mathfrak{H})$ and

$$
\begin{equation*}
\|K A\|_{1} \leq\|A\|\|K\|_{1}, \quad \text { respectively, } \quad\|A K\|_{1} \leq\|A\|\|K\|_{1} . \tag{6.25}
\end{equation*}
$$

Proof. Write $K=K_{1} K_{2}$ with $K_{1}, K_{2}$ Hilbert-Schmidt and use Corollary 6.11.

Now we can also explain the name trace class:
Lemma 6.15. If $K$ is trace class, then for any orthonormal basis $\left\{\varphi_{n}\right\}$ the trace

$$
\begin{equation*}
\operatorname{tr}(K)=\sum_{n}\left\langle\varphi_{n}, K \varphi_{n}\right\rangle \tag{6.26}
\end{equation*}
$$

is finite and independent of the orthonormal basis.
Proof. Let $\left\{\psi_{n}\right\}$ be another ONB. If we write $K=K_{1} K_{2}$ with $K_{1}, K_{2}$ Hilbert-Schmidt, we have

$$
\begin{aligned}
\sum_{n}\left\langle\varphi_{n}, K_{1} K_{2} \varphi_{n}\right\rangle & =\sum_{n}\left\langle K_{1}^{*} \varphi_{n}, K_{2} \varphi_{n}\right\rangle=\sum_{n, m}\left\langle K_{1}^{*} \varphi_{n}, \psi_{m}\right\rangle\left\langle\psi_{m}, K_{2} \varphi_{n}\right\rangle \\
& =\sum_{m, n}\left\langle K_{2}^{*} \psi_{m}, \varphi_{n}\right\rangle\left\langle\varphi_{n}, K_{1} \psi_{m}\right\rangle=\sum_{m}\left\langle K_{2}^{*} \psi_{m}, K_{1} \psi_{m}\right\rangle \\
& =\sum_{m}\left\langle\psi_{m}, K_{2} K_{1} \psi_{m}\right\rangle .
\end{aligned}
$$

Hence the trace is independent of the ONB and we even have $\operatorname{tr}\left(K_{1} K_{2}\right)=$ $\operatorname{tr}\left(K_{2} K_{1}\right)$.

Clearly for self-adjoint trace class operators, the trace is the sum over all eigenvalues (counted with their multiplicity). To see this, one just has to choose the orthonormal basis to consist of eigenfunctions. This is even true for all trace class operators and is known as Lidskij trace theorem (see [44] or [20] for an easy to read introduction).

Finally we note the following elementary properties of the trace:
Lemma 6.16. Suppose $K, K_{1}, K_{2}$ are trace class and $A$ is bounded.
(i) The trace is linear.
(ii) $\operatorname{tr}\left(K^{*}\right)=\operatorname{tr}(K)^{*}$.
(iii) If $K_{1} \leq K_{2}$, then $\operatorname{tr}\left(K_{1}\right) \leq \operatorname{tr}\left(K_{2}\right)$.
(iv) $\operatorname{tr}(A K)=\operatorname{tr}(K A)$.

Proof. (i) and (ii) are straightforward. (iii) follows from $K_{1} \leq K_{2}$ if and only if $\left\langle\varphi, K_{1} \varphi\right\rangle \leq\left\langle\varphi, K_{2} \varphi\right\rangle$ for every $\varphi \in \mathfrak{H}$. (iv) By Problem 6.7 and (i) it is no restriction to assume that $A$ is unitary. Let $\left\{\varphi_{n}\right\}$ be some ONB and note that $\left\{\psi_{n}=A \varphi_{n}\right\}$ is also an ONB. Then

$$
\begin{aligned}
\operatorname{tr}(A K) & =\sum_{n}\left\langle\psi_{n}, A K \psi_{n}\right\rangle=\sum_{n}\left\langle A \varphi_{n}, A K A \varphi_{n}\right\rangle \\
& =\sum_{n}\left\langle\varphi_{n}, K A \varphi_{n}\right\rangle=\operatorname{tr}(K A)
\end{aligned}
$$

and the claim follows.
Problem 6.7. Show that every bounded operator can be written as a linear combination of two self-adjoint operators. Furthermore, show that every bounded self-adjoint operator can be written as a linear combination of two unitary operators. (Hint: $x \pm \mathrm{i} \sqrt{1-x^{2}}$ has absolute value one for $x \in$ $[-1,1]$.)
Problem 6.8. Let $\mathfrak{H}=\ell^{2}(\mathbb{N})$ and let $A$ be multiplication by a sequence $a(n)$. Show that $A \in \mathcal{J}_{p}\left(\ell^{2}(\mathbb{N})\right)$ if and only if $a \in \ell^{p}(\mathbb{N})$. Furthermore, show that $\|A\|_{p}=\|a\|_{p}$ in this case.

Problem 6.9. Show that $A \geq 0$ is trace class if (6.26) is finite for one (and hence all) ONB. (Hint: $A$ is self-adjoint (why?) and $A=\sqrt{A} \sqrt{A}$.)

Problem 6.10. Show that for an orthogonal projection $P$ we have

$$
\operatorname{dim} \operatorname{Ran}(P)=\operatorname{tr}(P),
$$

where we set $\operatorname{tr}(P)=\infty$ if (6.26) is infinite (for one and hence all ONB by the previous problem).

Problem 6.11. Show that for $K \in \mathfrak{C}$ we have

$$
|K|=\sum_{j} s_{j}\left\langle\phi_{j}, .\right\rangle \phi_{j},
$$

where $|K|=\sqrt{K^{*} K}$. Conclude that

$$
\|K\|_{p}=\left(\operatorname{tr}\left(|A|^{p}\right)\right)^{1 / p} .
$$

Problem 6.12. Show that $K: \ell^{2}(\mathbb{N}) \rightarrow \ell^{2}(\mathbb{N}), f(n) \mapsto \sum_{j \in \mathbb{N}} k(n+j) f(j)$ is Hilbert-Schmidt with $\|K\|_{2} \leq\|c\|_{1}$ if $|k(n)| \leq c(n)$, where $c(n)$ is decreasing and summable.

### 6.4. Relatively compact operators and Weyl's theorem

In the previous section we have seen that the sum of a self-adjoint operator and a symmetric operator is again self-adjoint if the perturbing operator is small. In this section we want to study the influence of perturbations on the spectrum. Our hope is that at least some parts of the spectrum remain invariant.

We introduce some notation first. The discrete spectrum $\sigma_{d}(A)$ is the set of all eigenvalues which are discrete points of the spectrum and whose corresponding eigenspace is finite dimensional. The complement of the discrete spectrum is called the essential spectrum $\sigma_{e s s}(A)=\sigma(A) \backslash \sigma_{d}(A)$. If $A$ is self-adjoint, we might equivalently set

$$
\begin{equation*}
\sigma_{d}(A)=\left\{\lambda \in \sigma_{p}(A) \mid \operatorname{rank}\left(P_{A}((\lambda-\varepsilon, \lambda+\varepsilon))\right)<\infty \text { for some } \varepsilon>0\right\} \tag{6.27}
\end{equation*}
$$

respectively,

$$
\begin{equation*}
\sigma_{e s s}(A)=\left\{\lambda \in \mathbb{R} \mid \operatorname{rank}\left(P_{A}((\lambda-\varepsilon, \lambda+\varepsilon))\right)=\infty \text { for all } \varepsilon>0\right\} \tag{6.28}
\end{equation*}
$$

Example. For a self-adjoint compact operator $K$ we have by Theorem 6.6 that

$$
\begin{equation*}
\sigma_{e s s}(K) \subseteq\{0\} \tag{6.29}
\end{equation*}
$$

where equality holds if and only if $\mathfrak{H}$ is infinite dimensional.
Let $A$ be self-adjoint. Note that if we add a multiple of the identity to $A$, we shift the entire spectrum. Hence, in general, we cannot expect a (relatively) bounded perturbation to leave any part of the spectrum invariant. Next, if $\lambda_{0}$ is in the discrete spectrum, we can easily remove this eigenvalue with a finite rank perturbation of arbitrarily small norm. In fact, consider

$$
\begin{equation*}
A+\varepsilon P_{A}\left(\left\{\lambda_{0}\right\}\right) \tag{6.30}
\end{equation*}
$$

Hence our only hope is that the remainder, namely the essential spectrum, is stable under finite rank perturbations. To show this, we first need a good criterion for a point to be in the essential spectrum of $A$.

Lemma 6.17 (Weyl criterion). A point $\lambda$ is in the essential spectrum of a self-adjoint operator $A$ if and only if there is a sequence $\psi_{n}$ such that $\left\|\psi_{n}\right\|=1$, $\psi_{n}$ converges weakly to 0 , and $\left\|(A-\lambda) \psi_{n}\right\| \rightarrow 0$. Moreover, the sequence can be chosen orthonormal. Such a sequence is called a singular Weyl sequence.

Proof. Let $\psi_{n}$ be a singular Weyl sequence for the point $\lambda_{0}$. By Lemma 2.16 we have $\lambda_{0} \in \sigma(A)$ and hence it suffices to show $\lambda_{0} \notin \sigma_{d}(A)$. If $\lambda_{0} \in \sigma_{d}(A)$, we can find an $\varepsilon>0$ such that $P_{\varepsilon}=P_{A}\left(\left(\lambda_{0}-\varepsilon, \lambda_{0}+\varepsilon\right)\right)$ is finite rank. Consider $\tilde{\psi}_{n}=P_{\varepsilon} \psi_{n}$. Clearly $\left\|\left(A-\lambda_{0}\right) \tilde{\psi}_{n}\right\|=\left\|P_{\varepsilon}\left(A-\lambda_{0}\right) \psi_{n}\right\| \leq \|(A-$ $\left.\lambda_{0}\right) \psi_{n} \| \rightarrow 0$ and Lemma 6.8 (iii) implies $\tilde{\psi}_{n} \rightarrow 0$. However,

$$
\begin{aligned}
\left\|\psi_{n}-\tilde{\psi}_{n}\right\|^{2} & =\int_{\mathbb{R} \backslash(\lambda-\varepsilon, \lambda+\varepsilon)} d \mu_{\psi_{n}}(\lambda) \\
& \leq \frac{1}{\varepsilon^{2}} \int_{\mathbb{R} \backslash(\lambda-\varepsilon, \lambda+\varepsilon)}\left(\lambda-\lambda_{0}\right)^{2} d \mu_{\psi_{n}}(\lambda) \\
& \leq \frac{1}{\varepsilon^{2}}\left\|\left(A-\lambda_{0}\right) \psi_{n}\right\|^{2}
\end{aligned}
$$

and hence $\left\|\tilde{\psi}_{n}\right\| \rightarrow 1$, a contradiction.
Conversely, if $\lambda_{0} \in \sigma_{\text {ess }}(A)$, consider $P_{n}=P_{A}\left(\left[\lambda-\frac{1}{n}, \lambda-\frac{1}{n+1}\right) \cup(\lambda+\right.$ $\left.\left.\frac{1}{n+1}, \lambda+\frac{1}{n}\right]\right)$. Then $\operatorname{rank}\left(P_{n_{j}}\right)>0$ for an infinite subsequence $n_{j}$. Now pick $\psi_{j} \in \operatorname{Ran} P_{n_{j}}$.

Now let $K$ be a self-adjoint compact operator and $\psi_{n}$ a singular Weyl sequence for $A$. Then $\psi_{n}$ converges weakly to zero and hence

$$
\begin{equation*}
\left\|(A+K-\lambda) \psi_{n}\right\| \leq\left\|(A-\lambda) \psi_{n}\right\|+\left\|K \psi_{n}\right\| \rightarrow 0 \tag{6.31}
\end{equation*}
$$

since $\left\|(A-\lambda) \psi_{n}\right\| \rightarrow 0$ by assumption and $\left\|K \psi_{n}\right\| \rightarrow 0$ by Lemma 6.8 (iii). Hence $\sigma_{\text {ess }}(A) \subseteq \sigma_{\text {ess }}(A+K)$. Reversing the roles of $A+K$ and $A$ shows $\sigma_{\text {ess }}(A+K)=\sigma_{\text {ess }}(A)$. In particular, note that $A$ and $A+K$ have the same singular Weyl sequences.

Since we have shown that we can remove any point in the discrete spectrum by a self-adjoint finite rank operator, we obtain the following equivalent characterization of the essential spectrum.

Lemma 6.18. The essential spectrum of a self-adjoint operator $A$ is precisely the part which is invariant under compact perturbations. In particular,

$$
\begin{equation*}
\sigma_{\text {ess }}(A)=\bigcap_{K \in \mathfrak{C}(\mathfrak{F s}), K^{*}=K} \sigma(A+K) . \tag{6.32}
\end{equation*}
$$

There is even a larger class of operators under which the essential spectrum is invariant.

Theorem 6.19 (Weyl). Suppose $A$ and $B$ are self-adjoint operators. If

$$
\begin{equation*}
R_{A}(z)-R_{B}(z) \in \mathfrak{C}(\mathfrak{H}) \tag{6.33}
\end{equation*}
$$

for one $z \in \rho(A) \cap \rho(B)$, then

$$
\begin{equation*}
\sigma_{e s s}(A)=\sigma_{e s s}(B) . \tag{6.34}
\end{equation*}
$$

Proof. In fact, suppose $\lambda \in \sigma_{\text {ess }}(A)$ and let $\psi_{n}$ be a corresponding singular Weyl sequence. Then

$$
\left(R_{A}(z)-\frac{1}{\lambda-z}\right) \psi_{n}=\frac{R_{A}(z)}{z-\lambda}(A-\lambda) \psi_{n}
$$

and thus $\left\|\left(R_{A}(z)-\frac{1}{\lambda-z}\right) \psi_{n}\right\| \rightarrow 0$. Moreover, by our assumption we also have $\left\|\left(R_{B}(z)-\frac{1}{\lambda-z}\right) \psi_{n}\right\| \rightarrow 0$ and thus $\left\|(B-\lambda) \varphi_{n}\right\| \rightarrow 0$, where $\varphi_{n}=R_{B}(z) \psi_{n}$. Since

$$
\lim _{n \rightarrow \infty}\left\|\varphi_{n}\right\|=\lim _{n \rightarrow \infty}\left\|R_{A}(z) \psi_{n}\right\|=|\lambda-z|^{-1} \neq 0
$$

(since $\left.\left\|\left(R_{A}(z)-\frac{1}{\lambda-z}\right) \psi_{n}\right\|=\left\|\frac{1}{\lambda-z} R_{A}(z)(A-\lambda) \psi_{n}\right\| \rightarrow 0\right)$, we obtain a singular Weyl sequence for $B$, showing $\lambda \in \sigma_{\text {ess }}(B)$. Now interchange the roles of $A$ and $B$.

As a first consequence note the following result:
Theorem 6.20. Suppose $A$ is symmetric with equal finite defect indices. Then all self-adjoint extensions have the same essential spectrum.

Proof. By Lemma 2.29 the resolvent difference of two self-adjoint extensions is a finite rank operator if the defect indices are finite.

In addition, the following result is of interest.
Lemma 6.21. Suppose

$$
\begin{equation*}
R_{A}(z)-R_{B}(z) \in \mathfrak{C}(\mathfrak{H}) \tag{6.35}
\end{equation*}
$$

for one $z \in \rho(A) \cap \rho(B)$. Then this holds for all $z \in \rho(A) \cap \rho(B)$. In addition, if $A$ and $B$ are self-adjoint, then

$$
\begin{equation*}
f(A)-f(B) \in \mathfrak{C}(\mathfrak{H}) \tag{6.36}
\end{equation*}
$$

for all $f \in C_{\infty}(\mathbb{R})$.
Proof. If the condition holds for one $z$, it holds for all since we have (using both resolvent formulas)

$$
\begin{aligned}
& R_{A}\left(z^{\prime}\right)-R_{B}\left(z^{\prime}\right) \\
& \quad=\left(1-\left(z-z^{\prime}\right) R_{B}\left(z^{\prime}\right)\right)\left(R_{A}(z)-R_{B}(z)\right)\left(1-\left(z-z^{\prime}\right) R_{A}\left(z^{\prime}\right)\right) .
\end{aligned}
$$

Let $A$ and $B$ be self-adjoint. The set of all functions $f$ for which the claim holds is a closed $*$-subalgebra of $C_{\infty}(\mathbb{R})$ (with sup norm). Hence the claim follows from Lemma 4.4.

Remember that we have called $K$ relatively compact with respect to $A$ if $K R_{A}(z)$ is compact (for one and hence for all $z$ ) and note that the resolvent difference $R_{A+K}(z)-R_{A}(z)$ is compact if $K$ is relatively compact.

In particular, Theorem 6.19 applies if $B=A+K$, where $K$ is relatively compact.

For later use observe that the set of all operators which are relatively compact with respect to $A$ forms a linear space (since compact operators do) and relatively compact operators have $A$-bound zero.

Lemma 6.22. Let $A$ be self-adjoint and suppose $K$ is relatively compact with respect to $A$. Then the $A$-bound of $K$ is zero.

Proof. Write

$$
K R_{A}(\lambda \mathrm{i})=\left(K R_{A}(\mathrm{i})\right)\left((A+\mathrm{i}) R_{A}(\lambda \mathrm{i})\right)
$$

and observe that the first operator is compact and the second is normal and converges strongly to 0 (cf. Problem 3.7). Hence the claim follows from Lemma 6.3 and the discussion after Lemma 6.8 (since $R_{A}$ is normal).

In addition, note the following result which is a straightforward consequence of the second resolvent formula.

Lemma 6.23. Suppose $A$ is self-adjoint and $B$ is symmetric with $A$-bound less then one. If $K$ is relatively compact with respect to $A$, then it is also relatively compact with respect to $A+B$.

Proof. Since $B$ is $A$ bounded with $A$-bound less than one, we can choose a $z \in \mathbb{C}$ such that $\left\|B R_{A}(z)\right\|<1$ and hence

$$
\begin{equation*}
B R_{A+B}(z)=B R_{A}(z)\left(\mathbb{I}+B R_{A}(z)\right)^{-1} \tag{6.37}
\end{equation*}
$$

shows that $B$ is also $A+B$ bounded and the result follows from

$$
\begin{equation*}
K R_{A+B}(z)=K R_{A}(z)\left(\mathbb{I}-B R_{A+B}(z)\right) \tag{6.38}
\end{equation*}
$$

since $K R_{A}(z)$ is compact and $B R_{A+B}(z)$ is bounded.
Problem 6.13. Let $A$ and $B$ be self-adjoint operators. Suppose $B$ is relatively bounded with respect to $A$ and $A+B$ is self-adjoint. Show that if $|B|^{1 / 2} R_{A}(z)$ is Hilbert-Schmidt for one $z \in \rho(A)$, then this is true for all $z \in \rho(A)$. Moreover, $|B|^{1 / 2} R_{A+B}(z)$ is also Hilbert-Schmidt and $R_{A+B}(z)-$ $R_{A}(z)$ is trace class.

Problem 6.14. Show that $A=-\frac{d^{2}}{d x^{2}}+q(x), \mathfrak{D}(A)=H^{2}(\mathbb{R})$ is self-adjoint if $q \in L^{\infty}(\mathbb{R})$. Show that if $-u^{\prime \prime}(x)+q(x) u(x)=z u(x)$ has a solution for which $u$ and $u^{\prime}$ are bounded near $+\infty$ (or $-\infty$ ) but $u$ is not square integrable near $+\infty($ or $-\infty)$, then $z \in \sigma_{\text {ess }}(A)$. (Hint: Use $u$ to construct a Weyl sequence by restricting it to a compact set. Now modify your construction to get a singular Weyl sequence by observing that functions with disjoint support are orthogonal.)

### 6.5. Relatively form bounded operators and the KLMN theorem

In Section 6.1 we have considered the case where the operators $A$ and $B$ have a common domain on which the operator sum is well-defined. In this section we want to look at the case were this is no longer possible, but where it is still possible to add the corresponding quadratic forms. Under suitable conditions this form sum will give rise to an operator via Theorem 2.13.
Example. Let $A$ be the self-adjoint operator $A=-\frac{d^{2}}{d x^{2}}, \mathfrak{D}(A)=\{f \in$ $\left.H^{2}[0,1] \mid f(0)=f(1)=0\right\}$ in the Hilbert space $L^{2}(0,1)$. If we want to add a potential represented by a multiplication operator with a real-valued (measurable) function $q$, then we already have seen that $q$ will be relatively bounded if $q \in L^{2}(0,1)$. Hence, if $q \notin L^{2}(0,1)$, we are out of luck with the theory developed so far. On the other hand, if we look at the corresponding quadratic forms, we have $\mathfrak{Q}(A)=\left\{f \in H^{1}[0,1] \mid f(0)=f(1)=0\right\}$ and $\mathfrak{Q}(q)=\mathfrak{D}\left(|q|^{1 / 2}\right)$. Thus we see that $\mathfrak{Q}(A) \subset \mathfrak{Q}(q)$ if $q \in L^{1}(0,1)$.

In summary, the operators can be added if $q \in L^{2}(0,1)$ while the forms can be added under the less restrictive condition $q \in L^{1}(0,1)$.

Finally, note that in some drastic cases, there might even be no way to define the operator sum: Let $x_{j}$ be an enumeration of the rational numbers in $(0,1)$ and set

$$
q(x)=\sum_{j=1}^{\infty} \frac{1}{2^{j} \sqrt{\left|x-x_{j}\right|}},
$$

where the sum is to be understood as a limit in $L^{1}(0,1)$. Then $q$ gives rise to a self-adjoint multiplication operator in $L^{2}(0,1)$. However, note that $\mathfrak{D}(A) \cap \mathfrak{D}(q)=\{0\}$ ! In fact, let $f \in \mathfrak{D}(A) \cap \mathfrak{D}(q)$. Then $f$ is continuous and $q(x) f(x) \in L^{2}(0,1)$. Now suppose $f\left(x_{j}\right) \neq 0$ for some rational number $x_{j} \in(0,1)$. Then by continuity $|f(x)| \geq \delta$ for $x \in\left(x_{j}-\varepsilon, x_{j}+\varepsilon\right)$ and $q(x)|f(x)| \geq \delta 2^{-j}\left|x-x_{j}\right|^{-1 / 2}$ for $x \in\left(x_{j}-\varepsilon, x_{j}+\varepsilon\right)$ which shows that $q(x) f(x) \notin L^{2}(0,1)$ and hence $f$ must vanish at every rational point. By continuity, we conclude $f=0$.

Recall from Section 2.3 that every closed semi-bounded form $q=q_{A}$ corresponds to a self-adjoint operator $A$ (Theorem 2.13).

Given a self-adjoint operator $A \geq \gamma$ and a (hermitian) form $q: \mathfrak{Q} \rightarrow \mathbb{R}$ with $\mathfrak{Q}(A) \subseteq \mathfrak{Q}$, we call $q$ relatively form bound with respect to $q_{A}$ if there are constants $a, b \geq 0$ such that

$$
\begin{equation*}
|q(\psi)| \leq a q_{A-\gamma}(\psi)+b\|\psi\|^{2}, \quad \psi \in \mathfrak{Q}(A) \tag{6.39}
\end{equation*}
$$

The infimum of all possible $a$ is called the form bound of $q$ with respect to $q_{A}$.

Note that we do not require that $q$ is associated with some self-adjoint operator (though it will be in most cases).
Example. Let $A=-\frac{d^{2}}{d x^{2}}, \mathfrak{D}(A)=\left\{f \in H^{2}[0,1] \mid f(0)=f(1)=0\right\}$. Then

$$
q(f)=|f(c)|^{2}, \quad f \in H^{1}[0,1], \quad c \in(0,1),
$$

is a well-defined nonnegative form. Formally, one can interpret $q$ as the quadratic form of the multiplication operator with the delta distribution at $x=c$. But for $f \in \mathfrak{Q}(A)=\left\{f \in H^{1}[0,1] \mid f(0)=f(1)=0\right\}$ we have by Cauchy-Schwarz

$$
|f(c)|^{2}=2 \operatorname{Re} \int_{0}^{c} f(t)^{*} f^{\prime}(t) d t \leq 2 \int_{0}^{1}\left|f(t)^{*} f^{\prime}(t)\right| d t \leq \varepsilon\left\|f^{\prime}\right\|^{2}+\frac{1}{\varepsilon}\|f\|^{2} .
$$

Consequently $q$ is relatively bounded with bound 0 and hence $q_{A}+q$ gives rise to a well-defined operator as we will show in the next theorem.

The following result is the analog of the Kato-Rellich theorem and is due to Kato, Lions, Lax, Milgram, and Nelson.

Theorem 6.24 (KLMN). Suppose $q_{A}: \mathfrak{Q}(A) \rightarrow \mathbb{R}$ is a semi-bounded closed hermitian form and $q$ a relatively bounded hermitian form with relative bound less than one. Then $q_{A}+q$ defined on $\mathfrak{Q}(A)$ is closed and hence gives rise to a semi-bounded self-adjoint operator. Explicitly we have $q_{A}+q \geq(1-a) \gamma-b$.

Proof. A straightforward estimate shows $q_{A}(\psi)+q(\psi) \geq(1-a) q_{a}(\psi)-$ $b\|\psi\|^{2} \geq((1-a) \gamma-b)\|\psi\|^{2}$; that is, $q_{A}+q$ is semi-bounded. Moreover, by

$$
q_{A}(\psi) \leq \frac{1}{1-a}\left(\left|q_{A}(\psi)+q(\psi)\right|+b\|\psi\|^{2}\right)
$$

we see that the norms $\|\cdot\|_{q_{A}}$ and $\|\cdot\|_{q_{A}+q}$ are equivalent. Hence $q_{A}+q$ is closed and the result follows from Theorem 2.13.

In the investigation of the spectrum of the operator $A+B$ a key role is played by the second resolvent formula. In our present case we have the following analog.

Theorem 6.25. Suppose $A-\gamma \geq 0$ is self-adjoint and let $q$ be a hermitian form with $\mathfrak{Q}(q) \subseteq \mathfrak{Q}(A)$. Then the hermitian form

$$
\begin{equation*}
q\left(R_{A}(-\lambda)^{1 / 2} \psi\right), \quad \psi \in \mathfrak{H} \tag{6.40}
\end{equation*}
$$

corresponds to a bounded operator $C_{q}(\lambda)$ with $\left\|C_{q}(\lambda)\right\| \leq a$ for $\lambda>\frac{b}{a}-\gamma$ if and only if $q$ is relatively form bound with constants $a$ and $b$.

In particular, the form bound is given by

$$
\begin{equation*}
\lim _{\lambda \rightarrow \infty}\left\|C_{q}(\lambda)\right\| . \tag{6.41}
\end{equation*}
$$

Moreover, if $a<1$, then

$$
\begin{equation*}
R_{q_{A}+q}(-\lambda)=R_{A}(-\lambda)^{1 / 2}\left(1-C_{q}(\lambda)\right)^{-1} R_{A}(-\lambda)^{1 / 2} \tag{6.42}
\end{equation*}
$$

Here $R_{q_{A}+q}(z)$ is the resolvent of the self-adjoint operator corresponding to $q_{A}+q$.

Proof. We will abbreviate $C=C_{q}(\lambda)$ and $R_{A}^{1 / 2}=R_{A}(-\lambda)^{1 / 2}$. If $q$ is form bounded, we have for $\lambda>\frac{b}{a}-\gamma$ that

$$
\begin{aligned}
\left|q\left(R_{A}^{1 / 2} \psi\right)\right| & \leq a q_{A-\gamma}\left(R_{A}^{1 / 2} \psi\right)+b\left\|R_{A}^{1 / 2} \psi\right\|^{2} \\
& =a\left\langle\psi,\left(A-\gamma+\frac{b}{a}\right) R_{A}^{1 / 2} \psi\right\rangle \leq a\|\psi\|^{2}
\end{aligned}
$$

and hence $q\left(R_{A}^{1 / 2} \psi\right)$ corresponds to a bounded operator $C$. The converse is similar.

If $a<1$, then $(1-C)^{-1}$ is a well-defined bounded operator and so is $R=R_{A}^{1 / 2}(1-C)^{-1} R_{A}^{1 / 2}$. To see that $R$ is the inverse of $A_{1}-\lambda$, where $A_{1}$ is the operator associated with $q_{A}+q$, take $\varphi=R_{A}^{1 / 2} \tilde{\varphi} \in \mathfrak{Q}(A)$ and $\psi \in \mathfrak{H}$. Then

$$
\begin{aligned}
s_{A_{1}+\lambda}(\varphi, R \psi) & =s_{A+\lambda}(\varphi, R \psi)+s(\varphi, R \psi) \\
& =\left\langle\tilde{\varphi},(1+C)^{-1} R_{A}^{1 / 2} \psi\right\rangle+\left\langle\tilde{\varphi}, C(1+C)^{-1} R_{A}^{1 / 2} \psi\right\rangle=\langle\varphi, \psi\rangle
\end{aligned}
$$

Taking $\varphi \in \mathfrak{D}\left(A_{1}\right) \subseteq \mathfrak{Q}(A)$, we see $\left\langle\left(A_{1}+\lambda\right) \varphi, R \psi\right\rangle=\langle\varphi, \psi\rangle$ and thus $R=R_{A_{1}}(-\lambda)$ (Problem 6.15).

Furthermore, we can define $C_{q}(\lambda)$ for all $z \in \rho(A)$ using

$$
\begin{equation*}
C_{q}(z)=\left((A+\lambda)^{1 / 2} R_{A}(-z)^{1 / 2}\right)^{*} C_{q}(\lambda)(A+\lambda)^{1 / 2} R_{A}(-z)^{1 / 2} \tag{6.43}
\end{equation*}
$$

We will call $q$ relatively form compact if the operator $C_{q}(z)$ is compact for one and hence all $z \in \rho(A)$. As in the case of relatively compact operators we have

Lemma 6.26. Suppose $A-\gamma \geq 0$ is self-adjoint and let $q$ be a hermitian form. If $q$ is relatively form compact with respect to $q_{A}$, then its relative form bound is 0 and the resolvents of $q_{A}+q$ and $q_{A}$ differ by a compact operator.

In particular, by Weyl's theorem, the operators associated with $q_{A}$ and $q_{A}+q$ have the same essential spectrum.

Proof. Fix $\lambda_{0}>\frac{b}{a}-\gamma$ and let $\lambda \geq \lambda_{0}$. Consider the operator $D(\lambda)=$ $\left(A+\lambda_{0}\right)^{1 / 2} R_{A}(-\lambda)^{1 / 2}$ and note that $D(\lambda)$ is a bounded self-adjoint operator with $\|D(\lambda)\| \leq 1$. Moreover, $D(\lambda)$ converges strongly to 0 as $\lambda \rightarrow \infty$ (cf. Problem 3.7). Hence $\left\|D(\lambda) C\left(\lambda_{0}\right)\right\| \rightarrow 0$ by Lemma 6.8 and the same is true for $C(\lambda)=D(\lambda) C\left(\lambda_{0}\right) D(\lambda)$. So the relative bound is zero by (6.41).

Finally, the resolvent difference is compact by (6.42) since $(1+C)^{-1}=$ $1-C(1+C)^{-1}$.

Corollary 6.27. Suppose $A-\gamma \geq 0$ is self-adjoint and let $q_{1}, q_{2}$ be hermitian forms. If $q_{1}$ is relatively bounded with bound less than one and $q_{2}$ is relatively compact, then the resolvent difference of $q_{A}+q_{1}+q_{2}$ and $q_{A}+q_{1}$ is compact. In particular, the operators associated with $q_{A}+q_{1}$ and $q_{A}+q_{1}+q_{2}$ have the same essential spectrum.

Proof. Just observe that $C_{q_{1}+q_{2}}=C_{q_{1}}+C_{q_{2}}$ and $\left(1+C_{q_{1}}+C_{q_{2}}\right)^{-1}=$ $\left(1+C_{q_{1}}\right)^{-1}-\left(1+C_{q_{1}}\right)^{-1} C_{q_{2}}\left(1+C_{q_{1}}+C_{q_{2}}\right)^{-1}$.

Finally we turn to the special case where $q=q_{B}$ for some self-adjoint operator $B$. In this case we have

$$
\begin{equation*}
C_{B}(z)=\left(|B|^{1 / 2} R_{A}(-z)^{1 / 2}\right)^{*} \operatorname{sign}(B)|B|^{1 / 2} R_{A}(-z)^{1 / 2} \tag{6.44}
\end{equation*}
$$

and hence

$$
\begin{equation*}
\left\|C_{B}(z)\right\| \leq\left\||B|^{1 / 2} R_{A}(-z)^{1 / 2}\right\|^{2} \tag{6.45}
\end{equation*}
$$

with equality if $V \geq 0$. Thus the following result is not too surprising.
Lemma 6.28. Suppose $A-\gamma \geq 0$ and $B$ is self-adjoint. Then the following are equivalent:
(i) $B$ is $A$ form bounded.
(ii) $\mathfrak{Q}(A) \subseteq \mathfrak{Q}(B)$.
(iii) $|B|^{1 / 2} R_{A}(z)^{1 / 2}$ is bounded for one (and hence for all) $z \in \rho(A)$.

Proof. (i) $\Rightarrow$ (ii) is true by definition. (ii) $\Rightarrow$ (iii) since $|B|^{1 / 2} R_{A}(z)^{1 / 2}$ is a closed (Problem 2.9) operator defined on all of $\mathfrak{H}$ and hence bounded by the closed graph theorem (Theorem 2.8). To see (iii) $\Rightarrow$ (i), observe $|B|^{1 / 2} R_{A}(z)^{1 / 2}=|B|^{1 / 2} R_{A}\left(z_{0}\right)^{1 / 2}\left(A-z_{0}\right)^{1 / 2} R_{A}(z)^{1 / 2}$ which shows that $|B|^{1 / 2} R_{A}(z)^{1 / 2}$ is bounded for all $z \in \rho(A)$ if it is bounded for one $z_{0} \in \rho(A)$. But then (6.45) shows that (i) holds.

Clearly $C(\lambda)$ will be compact if $|B|^{1 / 2} R_{A}(z)^{1 / 2}$ is compact. However, since $R_{A}^{1 / 2}(z)$ might be hard to compute, we provide the following more handy criterion.

Lemma 6.29. Suppose $A-\gamma \geq 0$ and $B$ is self-adjoint where $B$ is relatively form bounded with bound less than one. Then the resolvent difference $R_{A+B}(z)-R_{A}(z)$ is compact if $|B|^{1 / 2} R_{A}(z)$ is compact and trace class if $|B|{ }^{1 / 2} R_{A}(z)$ is Hilbert-Schmidt.

Proof. Abbreviate $R_{A}=R_{A}(-\lambda), B_{1}=|B|^{1 / 2}, B_{2}=\operatorname{sign}(B)|B|^{1 / 2}$. Then we have $\left(1-C_{B}\right)^{-1}=1-\left(B_{1} R_{A}^{1 / 2}\right)^{*}\left(1+\tilde{C}_{B}\right)^{-1} B_{2} R_{A}^{1 / 2}$, where $\tilde{C}_{B}=$ $B_{2} R_{A}^{1 / 2}\left(B_{1} R_{A}^{1 / 2}\right)^{*}$. Hence $R_{A+B}-R_{A}=\left(B_{1} R_{A}\right)^{*}\left(1+\tilde{C}_{B}\right)^{-1} B_{2} R_{A}$ and the claim follows.

Moreover, the second resolvent formula still holds when interpreted suitably:

Lemma 6.30. Suppose $A-\gamma \geq 0$ and $B$ is self-adjoint. If $\mathfrak{Q}(A) \subseteq \mathfrak{Q}(B)$ and $q_{A}+q_{B}$ is a closed semi-bounded form. Then

$$
\begin{align*}
R_{A+B}(z) & =R_{A}(z)-\left(|B|^{1 / 2} R_{A+B}\left(z^{*}\right)\right)^{*} \operatorname{sign}(B)|B|^{1 / 2} R_{A}(z) \\
& =R_{A}(z)-\left(|B|^{1 / 2} R_{A}\left(z^{*}\right)\right)^{*} \operatorname{sign}(B)|B|^{1 / 2} R_{A+B}(z) \tag{6.46}
\end{align*}
$$

for $z \in \rho(A) \cap \rho(A+B)$. Here $A+B$ is the self-adjoint operator associated with $q_{A}+q_{B}$.

Proof. Let $\varphi \in \mathfrak{D}(A+B)$ and $\psi \in \mathfrak{H}$. Denote the right-hand side in (6.46) by $R(z)$ and abbreviate $R=R(z), R_{A}=R_{A}(z), B_{1}=|B|^{1 / 2}, B_{2}=$ $\operatorname{sign}(B)|B|^{1 / 2}$. Then, using $s_{A+B-z}(\varphi, \psi)=\left\langle\left(A+B+z^{*}\right) \varphi, \psi\right\rangle$,

$$
\begin{aligned}
s_{A+B-z}(\varphi, R \psi) & =s_{A+B-z}\left(\varphi, R_{A} \psi\right)-\left\langle B_{1} R_{A+B}^{*}\left(A+B+z^{*}\right) \varphi, B_{2} R_{A} \psi\right\rangle \\
& =s_{A+B-z}\left(\varphi, R_{A} \psi\right)-s_{B}\left(\varphi, R_{A} \psi\right)=s_{A-z}\left(\varphi, R_{A} \psi\right) \\
& =\langle\varphi, \psi\rangle .
\end{aligned}
$$

Thus $R=R_{A+B}(z)$ (Problem 6.15). The second equality follows after exchanging the roles of $A$ and $A+B$.

It can be shown using abstract interpolation techniques that if $B$ is relatively bounded with respect to $A$, then it is also relatively form bounded. In particular, if $B$ is relatively bounded, then $B R_{A}(z)$ is bounded and it is not hard to check that (6.46) coincides with (6.4). Consequently $A+B$ defined as operator sum is the same as $A+B$ defined as form sum.

Problem 6.15. Suppose $A$ is closed and $R$ is bounded. Show that $R=$ $R_{A}(z)$ if and only if $\left\langle(A-z)^{*} \varphi, R \psi\right\rangle=\langle\varphi, \psi\rangle$ for all $\varphi \in \mathfrak{D}\left(A^{*}\right), \psi \in \mathfrak{H}$.

Problem 6.16. Let $q$ be relatively form bounded with constants a and $b$. Show that $C_{q}(\lambda)$ satisfies $\|C(\lambda)\| \leq \max \left(a, \frac{b}{\lambda+\gamma}\right)$ for $\lambda>-\gamma$. Furthermore, show that $\|C(\lambda)\|$ decreases as $\lambda \rightarrow \infty$.

### 6.6. Strong and norm resolvent convergence

Suppose $A_{n}$ and $A$ are self-adjoint operators. We say that $A_{n}$ converges to $A$ in the norm, respectively, strong resolvent sense, if

$$
\begin{equation*}
\lim _{n \rightarrow \infty} R_{A_{n}}(z)=R_{A}(z), \quad \text { respectively, } \quad \underset{n \rightarrow \infty}{\text { s-lim }} R_{A_{n}}(z)=R_{A}(z) \tag{6.47}
\end{equation*}
$$

for one $z \in \Gamma=\mathbb{C} \backslash \Sigma, \Sigma=\sigma(A) \cup \bigcup_{n} \sigma\left(A_{n}\right)$. In fact, in the case of strong resolvent convergence it will be convenient to include the case if $A_{n}$ is only defined on some subspace $\mathfrak{H}_{n} \subseteq \mathfrak{H}$, where we require $P_{n} \xrightarrow{s} 1$ for the orthogonal projection onto $\mathfrak{H}_{n}$. In this case $R_{A_{n}}(z)$ (respectively, any other function of $A_{n}$ ) has to be understood as $R_{A_{n}}(z) P_{n}$, where $P_{n}$ is the orthogonal projector onto $\mathfrak{H}_{n}$. (This generalization will produce nothing new in the norm case, since $P_{n} \rightarrow 1$ implies $P_{n}=1$ for sufficiently large $n$.)

Using the Stone-Weierstraß theorem, we obtain as a first consequence
Theorem 6.31. Suppose $A_{n}$ converges to $A$ in the norm resolvent sense. Then $f\left(A_{n}\right)$ converges to $f(A)$ in norm for any bounded continuous function $f: \Sigma \rightarrow \mathbb{C}$ with $\lim _{\lambda \rightarrow-\infty} f(\lambda)=\lim _{\lambda \rightarrow \infty} f(\lambda)$.

If $A_{n}$ converges to $A$ in the strong resolvent sense, then $f\left(A_{n}\right)$ converges to $f(A)$ strongly for any bounded continuous function $f: \Sigma \rightarrow \mathbb{C}$.

Proof. The set of functions for which the claim holds clearly forms a *subalgebra (since resolvents are normal, taking adjoints is continuous even with respect to strong convergence) and since it contains $f(\lambda)=1$ and $f(\lambda)=\frac{1}{\lambda-z_{0}}$, this $*$-subalgebra is dense by the Stone-Weierstraß theorem (cf. Problem 1.21). The usual $\frac{\varepsilon}{3}$ argument shows that this $*$-subalgebra is also closed.

It remains to show the strong resolvent case for arbitrary bounded continuous functions. Let $\chi_{n}$ be a compactly supported continuous function $\left(0 \leq \chi_{m} \leq 1\right)$ which is one on the interval $[-m, m]$. Then $\chi_{m}\left(A_{n}\right) \xrightarrow{s} \chi_{m}(A)$, $f\left(A_{n}\right) \chi_{m}\left(A_{n}\right) \xrightarrow{s} f(A) \chi_{m}(A)$ by the first part and hence

$$
\begin{aligned}
\left\|\left(f\left(A_{n}\right)-f(A)\right) \psi\right\| \leq & \left\|f\left(A_{n}\right)\right\|\left\|\left(1-\chi_{m}(A)\right) \psi\right\| \\
& +\left\|f\left(A_{n}\right)\right\|\left\|\left(\chi_{m}(A)-\chi_{m}\left(A_{n}\right)\right) \psi\right\| \\
& +\left\|\left(f\left(A_{n}\right) \chi_{m}\left(A_{n}\right)-f(A) \chi_{m}(A)\right) \psi\right\| \\
& +\|f(A)\|\left\|\left(1-\chi_{m}(A)\right) \psi\right\|
\end{aligned}
$$

can be made arbitrarily small since $\|f().\| \leq\|f\|_{\infty}$ and $\chi_{m}(.) \xrightarrow{s} \mathbb{I}$ by Theorem 3.1.

As a consequence, note that the point $z \in \Gamma$ is of no importance, that is,

Corollary 6.32. Suppose $A_{n}$ converges to $A$ in the norm or strong resolvent sense for one $z_{0} \in \Gamma$. Then this holds for all $z \in \Gamma$.

Also,
Corollary 6.33. Suppose $A_{n}$ converges to $A$ in the strong resolvent sense. Then

$$
\begin{equation*}
\mathrm{e}^{\mathrm{i} t A_{n}} \xrightarrow{s} \mathrm{e}^{\mathrm{i} t A}, \quad t \in \mathbb{R}, \tag{6.48}
\end{equation*}
$$

and if all operators are semi-bounded by the same bound

$$
\begin{equation*}
\mathrm{e}^{-t A_{n}} \xrightarrow{s} \mathrm{e}^{-t A}, \quad t \geq 0 \tag{6.49}
\end{equation*}
$$

Next we need some good criteria to check for norm, respectively, strong, resolvent convergence.

Lemma 6.34. Let $A_{n}$, $A$ be self-adjoint operators with $\mathfrak{D}\left(A_{n}\right)=\mathfrak{D}(A)$. Then $A_{n}$ converges to $A$ in the norm resolvent sense if there are sequences $a_{n}$ and $b_{n}$ converging to zero such that

$$
\begin{equation*}
\left\|\left(A_{n}-A\right) \psi\right\| \leq a_{n}\|\psi\|+b_{n}\|A \psi\|, \quad \psi \in \mathfrak{D}(A)=\mathfrak{D}\left(A_{n}\right) . \tag{6.50}
\end{equation*}
$$

Proof. From the second resolvent formula

$$
R_{A_{n}}(z)-R_{A}(z)=R_{A_{n}}(z)\left(A-A_{n}\right) R_{A}(z),
$$

we infer

$$
\begin{aligned}
\left\|\left(R_{A_{n}}(\mathrm{i})-R_{A}(\mathrm{i})\right) \psi\right\| & \leq\left\|R_{A_{n}}(\mathrm{i})\right\|\left(a_{n}\left\|R_{A}(\mathrm{i}) \psi\right\|+b_{n}\left\|A R_{A}(\mathrm{i}) \psi\right\|\right) \\
& \leq\left(a_{n}+b_{n}\right)\|\psi\|
\end{aligned}
$$

and hence $\left\|R_{A_{n}}(\mathrm{i})-R_{A}(\mathrm{i})\right\| \leq a_{n}+b_{n} \rightarrow 0$.
In particular, norm convergence implies norm resolvent convergence:
Corollary 6.35. Let $A_{n}$, $A$ be bounded self-adjoint operators with $A_{n} \rightarrow A$. Then $A_{n}$ converges to $A$ in the norm resolvent sense.

Similarly, if no domain problems get in the way, strong convergence implies strong resolvent convergence:

Lemma 6.36. Let $A_{n}, A$ be self-adjoint operators. Then $A_{n}$ converges to $A$ in the strong resolvent sense if there is a core $\mathfrak{D}_{0}$ of $A$ such that for any $\psi \in \mathfrak{D}_{0}$ we have $P_{n} \psi \in \mathfrak{D}\left(A_{n}\right)$ for $n$ sufficiently large and $A_{n} \psi \rightarrow A \psi$.

Proof. We begin with the case $\mathfrak{H}_{n}=\mathfrak{H}$. Using the second resolvent formula, we have

$$
\left\|\left(R_{A_{n}}(\mathrm{i})-R_{A}(\mathrm{i})\right) \psi\right\| \leq\left\|\left(A-A_{n}\right) R_{A}(\mathrm{i}) \psi\right\| \rightarrow 0
$$

for $\psi \in(A-\mathrm{i}) \mathfrak{D}_{0}$ which is dense, since $\mathfrak{D}_{0}$ is a core. The rest follows from Lemma 1.14.

If $\mathfrak{H}_{n} \subset \mathfrak{H}$, we can consider $\tilde{A}_{n}=A_{n} \oplus 0$ and conclude $R_{\tilde{A_{n}}}(\mathrm{i}) \xrightarrow{s} R_{A}(\mathrm{i})$ from the first case. By $R_{\tilde{A_{n}}}(\mathrm{i})=R_{A_{n}}(\mathrm{i})-\mathrm{i}\left(1-P_{n}\right)$ the same is true for $R_{A_{n}}(\mathrm{i})$ since $1-P_{n} \xrightarrow{s} 0$ by assumption.

If you wonder why we did not define weak resolvent convergence, here is the answer: it is equivalent to strong resolvent convergence.

Lemma 6.37. Suppose $\mathrm{w}-\lim _{n \rightarrow \infty} R_{A_{n}}(z)=R_{A}(z)$ for some $z \in \Gamma$. Then s- $\lim _{n \rightarrow \infty} R_{A_{n}}(z)=R_{A}(z)$ also.

Proof. By $R_{A_{n}}(z) \rightharpoonup R_{A}(z)$ we also have $R_{A_{n}}(z)^{*} \rightharpoonup R_{A}(z)^{*}$ and thus by the first resolvent formula

$$
\begin{gathered}
\left\|R_{A_{n}}(z) \psi\right\|^{2}-\left\|R_{A}(z) \psi\right\|^{2}=\left\langle\psi, R_{A_{n}}\left(z^{*}\right) R_{A_{n}}(z) \psi-R_{A}\left(z^{*}\right) R_{A}(z) \psi\right\rangle \\
=\frac{1}{z-z^{*}}\left\langle\psi,\left(R_{A_{n}}(z)-R_{A_{n}}\left(z^{*}\right)+R_{A}(z)-R_{A}\left(z^{*}\right)\right) \psi\right\rangle \rightarrow 0 .
\end{gathered}
$$

Together with $R_{A_{n}}(z) \psi \rightharpoonup R_{A}(z) \psi$ we have $R_{A_{n}}(z) \psi \rightarrow R_{A}(z) \psi$ by virtue of Lemma 1.12 (iv).

Now what can we say about the spectrum?
Theorem 6.38. Let $A_{n}$ and $A$ be self-adjoint operators. If $A_{n}$ converges to $A$ in the strong resolvent sense, we have $\sigma(A) \subseteq \lim _{n \rightarrow \infty} \sigma\left(A_{n}\right)$. If $A_{n}$ converges to $A$ in the norm resolvent sense, we have $\sigma(A)=\lim _{n \rightarrow \infty} \sigma\left(A_{n}\right)$.

Proof. Suppose the first claim were incorrect. Then we can find a $\lambda \in \sigma(A)$ and some $\varepsilon>0$ such that $\sigma\left(A_{n}\right) \cap(\lambda-\varepsilon, \lambda+\varepsilon)=\emptyset$. Choose a bounded continuous function $f$ which is one on $\left(\lambda-\frac{\varepsilon}{2}, \lambda+\frac{\varepsilon}{2}\right)$ and which vanishes outside $(\lambda-\varepsilon, \lambda+\varepsilon)$. Then $f\left(A_{n}\right)=0$ and hence $f(A) \psi=\lim f\left(A_{n}\right) \psi=0$ for every $\psi$. On the other hand, since $\lambda \in \sigma(A)$, there is a nonzero $\psi \in$ Ran $P_{A}\left(\left(\lambda-\frac{\varepsilon}{2}, \lambda+\frac{\varepsilon}{2}\right)\right)$ implying $f(A) \psi=\psi$, a contradiction.

To see the second claim, recall that the norm of $R_{A}(z)$ is just one over the distance from the spectrum. In particular, $\lambda \notin \sigma(A)$ if and only if $\left\|R_{A}(\lambda+\mathrm{i})\right\|<1$. So $\lambda \notin \sigma(A)$ implies $\left\|R_{A}(\lambda+\mathrm{i})\right\|<1$, which implies $\left\|R_{A_{n}}(\lambda+\mathrm{i})\right\|<1$ for $n$ sufficiently large, which implies $\lambda \notin \sigma\left(A_{n}\right)$ for $n$ sufficiently large.

Example. Note that the spectrum can contract if we only have convergence in the strong resolvent sense: Let $A_{n}$ be multiplication by $\frac{1}{n} x$ in $L^{2}(\mathbb{R})$. Then $A_{n}$ converges to 0 in the strong resolvent sense, but $\sigma\left(A_{n}\right)=\mathbb{R}$ and $\sigma(0)=\{0\}$.

Lemma 6.39. Suppose $A_{n}$ converges in the strong resolvent sense to $A$. If $P_{A}(\{\lambda\})=0$, then

$$
\begin{equation*}
{\underset{n \rightarrow \infty}{\mathrm{~s}-\lim _{\infty}} P_{A_{n}}((-\infty, \lambda))=\operatorname{silim}_{n \rightarrow \infty} P_{A_{n}}((-\infty, \lambda])=P_{A}((-\infty, \lambda))=P_{A}((-\infty, \lambda]) . . . ~} \tag{6.51}
\end{equation*}
$$

Proof. By Theorem 6.31 the spectral measures $\mu_{n, \psi}$ corresponding to $A_{n}$ converge vaguely to those of $A$. Hence $\left\|P_{A_{n}}(\Omega) \psi\right\|^{2}=\mu_{n, \psi}(\Omega)$ together with Lemma A. 25 implies the claim.

Using $P\left(\left(\lambda_{0}, \lambda_{1}\right)\right)=P\left(\left(-\infty, \lambda_{1}\right)\right)-P\left(\left(-\infty, \lambda_{0}\right]\right)$, we also obtain the following.

Corollary 6.40. Suppose $A_{n}$ converges in the strong resolvent sense to $A$. If $P_{A}\left(\left\{\lambda_{0}\right\}\right)=P_{A}\left(\left\{\lambda_{1}\right\}\right)=0$, then

$$
\begin{equation*}
\underset{n \rightarrow \infty}{\mathrm{~s}-\lim } P_{A_{n}}\left(\left(\lambda_{0}, \lambda_{1}\right)\right)=\underset{n \rightarrow \infty}{\operatorname{s-lim}} P_{A_{n}}\left(\left[\lambda_{0}, \lambda_{1}\right]\right)=P_{A}\left(\left(\lambda_{0}, \lambda_{1}\right)\right)=P_{A}\left(\left[\lambda_{0}, \lambda_{1}\right]\right) \tag{6.52}
\end{equation*}
$$

Example. The following example shows that the requirement $P_{A}(\{\lambda\})=0$ is crucial, even if we have bounded operators and norm convergence. In fact, let $\mathfrak{H}=\mathbb{C}^{2}$ and

$$
A_{n}=\frac{1}{n}\left(\begin{array}{cc}
1 & 0  \tag{6.53}\\
0 & -1
\end{array}\right)
$$

Then $A_{n} \rightarrow 0$ and

$$
P_{A_{n}}((-\infty, 0))=P_{A_{n}}((-\infty, 0])=\left(\begin{array}{ll}
0 & 0  \tag{6.54}\\
0 & 1
\end{array}\right)
$$

but $P_{0}((-\infty, 0))=0$ and $P_{0}((-\infty, 0])=\mathbb{I}$.
Problem 6.17. Show that for self-adjoint operators, strong resolvent convergence is equivalent to convergence with respect to the metric

$$
\begin{equation*}
d(A, B)=\sum_{n \in \mathbb{N}} \frac{1}{2^{n}}\left\|\left(R_{A}(\mathrm{i})-R_{B}(\mathrm{i})\right) \varphi_{n}\right\| \tag{6.55}
\end{equation*}
$$

where $\left\{\varphi_{n}\right\}_{n \in \mathbb{N}}$ is some (fixed) ONB.
Problem 6.18 (Weak convergence of spectral measures). Suppose $A_{n} \rightarrow A$ in the strong resolvent sense and let $\mu_{n, \psi}, \mu_{\psi}$ be the corresponding spectral measures. Show that

$$
\begin{equation*}
\int f(\lambda) d \mu_{n, \psi}(\lambda) \rightarrow \int f(\lambda) d \mu_{\psi}(\lambda) \tag{6.56}
\end{equation*}
$$

for every bounded continuous $f$. Give a counterexample when $f$ is not continuous.

## Part 2

## Schrödinger Operators

## The free Schrödinger operator

### 7.1. The Fourier transform

We first review some basic facts concerning the Fourier transform which will be needed in the following section.

Let $C^{\infty}\left(\mathbb{R}^{n}\right)$ be the set of all complex-valued functions which have partial derivatives of arbitrary order. For $f \in C^{\infty}\left(\mathbb{R}^{n}\right)$ and $\alpha \in \mathbb{N}_{0}^{n}$ we set

$$
\begin{equation*}
\partial_{\alpha} f=\frac{\partial^{|\alpha|} f}{\partial x_{1}^{\alpha_{1}} \cdots \partial x_{n}^{\alpha_{n}}}, \quad x^{\alpha}=x_{1}^{\alpha_{1}} \cdots x_{n}^{\alpha_{n}}, \quad|\alpha|=\alpha_{1}+\cdots+\alpha_{n} \tag{7.1}
\end{equation*}
$$

An element $\alpha \in \mathbb{N}_{0}^{n}$ is called a multi-index and $|\alpha|$ is called its order. Recall the Schwartz space

$$
\begin{equation*}
\mathcal{S}\left(\mathbb{R}^{n}\right)=\left\{f \in C^{\infty}\left(\mathbb{R}^{n}\right)\left|\sup _{x}\right| x^{\alpha}\left(\partial_{\beta} f\right)(x) \mid<\infty, \alpha, \beta \in \mathbb{N}_{0}^{n}\right\} \tag{7.2}
\end{equation*}
$$

which is dense in $L^{2}\left(\mathbb{R}^{n}\right)$ (since $C_{c}^{\infty}\left(\mathbb{R}^{n}\right) \subset \mathcal{S}\left(\mathbb{R}^{n}\right)$ is). Note that if $f \in$ $\mathcal{S}\left(\mathbb{R}^{n}\right)$, then the same is true for $x^{\alpha} f(x)$ and $\left(\partial_{\alpha} f\right)(x)$ for any multi-index $\alpha$. For $f \in \mathcal{S}\left(\mathbb{R}^{n}\right)$ we define

$$
\begin{equation*}
\mathcal{F}(f)(p) \equiv \hat{f}(p)=\frac{1}{(2 \pi)^{n / 2}} \int_{\mathbb{R}^{n}} \mathrm{e}^{-\mathrm{i} p x} f(x) d^{n} x . \tag{7.3}
\end{equation*}
$$

Then,
Lemma 7.1. The Fourier transform maps the Schwartz space into itself, $\mathcal{F}: \mathcal{S}\left(\mathbb{R}^{n}\right) \rightarrow \mathcal{S}\left(\mathbb{R}^{n}\right)$. Furthermore, for any multi-index $\alpha \in \mathbb{N}_{0}^{n}$ and any $f \in \mathcal{S}\left(\mathbb{R}^{n}\right)$ we have

$$
\begin{equation*}
\left(\partial_{\alpha} f\right)^{\wedge}(p)=(\mathrm{i} p)^{\alpha} \hat{f}(p), \quad\left(x^{\alpha} f(x)\right)^{\wedge}(p)=\mathrm{i}^{|\alpha|} \partial_{\alpha} \hat{f}(p) \tag{7.4}
\end{equation*}
$$

Proof. First of all, by integration by parts, we see

$$
\begin{aligned}
\left(\frac{\partial}{\partial x_{j}} f(x)\right)^{\wedge}(p) & =\frac{1}{(2 \pi)^{n / 2}} \int_{\mathbb{R}^{n}} \mathrm{e}^{-\mathrm{i} p x} \frac{\partial}{\partial x_{j}} f(x) d^{n} x \\
& =\frac{1}{(2 \pi)^{n / 2}} \int_{\mathbb{R}^{n}}\left(-\frac{\partial}{\partial x_{j}} \mathrm{e}^{-\mathrm{i} p x}\right) f(x) d^{n} x \\
& =\frac{1}{(2 \pi)^{n / 2}} \int_{\mathbb{R}^{n}} \mathrm{i} p_{j} \mathrm{e}^{-\mathrm{i} p x} f(x) d^{n} x=\mathrm{i} p_{j} \hat{f}(p) .
\end{aligned}
$$

So the first formula follows by induction.
Similarly, the second formula follows from induction using

$$
\begin{aligned}
\left(x_{j} f(x)\right)^{\wedge}(p) & =\frac{1}{(2 \pi)^{n / 2}} \int_{\mathbb{R}^{n}} x_{j} \mathrm{e}^{-\mathrm{i} p x} f(x) d^{n} x \\
& =\frac{1}{(2 \pi)^{n / 2}} \int_{\mathbb{R}^{n}}\left(\mathrm{i} \frac{\partial}{\partial p_{j}} \mathrm{e}^{-\mathrm{i} p x}\right) f(x) d^{n} x=\mathrm{i} \frac{\partial}{\partial p_{j}} \hat{f}(p),
\end{aligned}
$$

where interchanging the derivative and integral is permissible by Problem A.8. In particular, $\hat{f}(p)$ is differentiable.

To see that $\hat{f} \in \mathcal{S}\left(\mathbb{R}^{n}\right)$ if $f \in \mathcal{S}\left(\mathbb{R}^{n}\right)$, we begin with the observation that $\hat{f}$ is bounded; in fact, $\|\hat{f}\|_{\infty} \leq(2 \pi)^{-n / 2}\|f\|_{1}$. But then $p^{\alpha}\left(\partial_{\beta} \hat{f}\right)(p)=$ $\mathrm{i}^{-|\alpha|-|\beta|}\left(\partial^{\alpha} x^{\beta} f(x)\right)^{\wedge}(p)$ is bounded since $\partial^{\alpha} x^{\beta} f(x) \in \mathcal{S}\left(\mathbb{R}^{n}\right)$ if $f \in \mathcal{S}\left(\mathbb{R}^{n}\right)$.

Hence we will sometimes write $p f(x)$ for $-\mathrm{i} \partial f(x)$, where $\partial=\left(\partial_{1}, \ldots, \partial_{n}\right)$ is the gradient.

Two more simple properties are left as an exercise.
Lemma 7.2. Let $f \in \mathcal{S}\left(\mathbb{R}^{n}\right)$. Then

$$
\begin{align*}
(f(x+a))^{\wedge}(p) & =\mathrm{e}^{\mathrm{i} a p} \hat{f}(p), & & a \in \mathbb{R}^{n},  \tag{7.5}\\
(f(\lambda x))^{\wedge}(p) & =\frac{1}{\lambda^{n}} \hat{f}\left(\frac{p}{\lambda}\right), & & \lambda>0 . \tag{7.6}
\end{align*}
$$

Next, we want to compute the inverse of the Fourier transform. For this the following lemma will be needed.
Lemma 7.3. We have $\mathrm{e}^{-z x^{2} / 2} \in \mathcal{S}\left(\mathbb{R}^{n}\right)$ for $\operatorname{Re}(z)>0$ and

$$
\begin{equation*}
\mathcal{F}\left(\mathrm{e}^{-z x^{2} / 2}\right)(p)=\frac{1}{z^{n / 2}} \mathrm{e}^{-p^{2} /(2 z)} . \tag{7.7}
\end{equation*}
$$

Here $z^{n / 2}$ has to be understood as $(\sqrt{z})^{n}$, where the branch cut of the root is chosen along the negative real axis.

Proof. Due to the product structure of the exponential, one can treat each coordinate separately, reducing the problem to the case $n=1$.

Let $\phi_{z}(x)=\exp \left(-z x^{2} / 2\right)$. Then $\phi_{z}^{\prime}(x)+z x \phi_{z}(x)=0$ and hence $\mathrm{i}\left(p \hat{\phi}_{z}(p)+\right.$ $\left.z \hat{\phi}_{z}^{\prime}(p)\right)=0$. Thus $\hat{\phi}_{z}(p)=c \phi_{1 / z}(p)$ and (Problem 7.1)

$$
c=\hat{\phi}_{z}(0)=\frac{1}{\sqrt{2 \pi}} \int_{\mathbb{R}} \exp \left(-z x^{2} / 2\right) d x=\frac{1}{\sqrt{z}}
$$

at least for $z>0$. However, since the integral is holomorphic for $\operatorname{Re}(z)>0$ by Problem A.10, this holds for all $z$ with $\operatorname{Re}(z)>0$ if we choose the branch cut of the root along the negative real axis.

Now we can show
Theorem 7.4. The Fourier transform $\mathcal{F}: \mathcal{S}\left(\mathbb{R}^{n}\right) \rightarrow \mathcal{S}\left(\mathbb{R}^{n}\right)$ is a bijection. Its inverse is given by

$$
\begin{equation*}
\mathcal{F}^{-1}(g)(x) \equiv \check{g}(x)=\frac{1}{(2 \pi)^{n / 2}} \int_{\mathbb{R}^{n}} \mathrm{e}^{\mathrm{i} p x} g(p) d^{n} p \tag{7.8}
\end{equation*}
$$

We have $\mathcal{F}^{2}(f)(x)=f(-x)$ and thus $\mathcal{F}^{4}=\mathbb{I}$.
Proof. Abbreviate $\phi_{\varepsilon}(x)=\exp \left(-\varepsilon x^{2} / 2\right)$. By dominated convergence we have

$$
\begin{aligned}
(\hat{f}(p))^{\vee}(x) & =\frac{1}{(2 \pi)^{n / 2}} \int_{\mathbb{R}^{n}} \mathrm{e}^{\mathrm{i} p x} \hat{f}(p) d^{n} p \\
& =\lim _{\varepsilon \rightarrow 0} \frac{1}{(2 \pi)^{n / 2}} \int_{\mathbb{R}^{n}} \phi_{\varepsilon}(p) \mathrm{e}^{\mathrm{i} p x} \hat{f}(p) d^{n} p \\
& =\lim _{\varepsilon \rightarrow 0} \frac{1}{(2 \pi)^{n}} \int_{\mathbb{R}^{n}} \int_{\mathbb{R}^{n}} \phi_{\varepsilon}(p) \mathrm{e}^{\mathrm{i} p x} f(y) \mathrm{e}^{-\mathrm{i} p x} d^{n} y d^{n} p,
\end{aligned}
$$

and, invoking Fubini and Lemma 7.2, we further see

$$
\begin{aligned}
& =\lim _{\varepsilon \rightarrow 0} \frac{1}{(2 \pi)^{n / 2}} \int_{\mathbb{R}^{n}}\left(\phi_{\varepsilon}(p) \mathrm{e}^{\mathrm{i} p x}\right)^{\wedge}(y) f(y) d^{n} y \\
& =\lim _{\varepsilon \rightarrow 0} \frac{1}{(2 \pi)^{n / 2}} \int_{\mathbb{R}^{n}} \frac{1}{\varepsilon^{n / 2}} \phi_{1 / \varepsilon}(y-x) f(y) d^{n} y \\
& =\lim _{\varepsilon \rightarrow 0} \frac{1}{(2 \pi)^{n / 2}} \int_{\mathbb{R}^{n}} \phi_{1}(z) f(x+\sqrt{\varepsilon} z) d^{n} z=f(x),
\end{aligned}
$$

which finishes the proof, where we used the change of coordinates $z=\frac{y-x}{\sqrt{\varepsilon}}$ and again dominated convergence in the last two steps.

From Fubini's theorem we also obtain Parseval's identity

$$
\begin{align*}
\int_{\mathbb{R}^{n}}|\hat{f}(p)|^{2} d^{n} p & =\frac{1}{(2 \pi)^{n / 2}} \int_{\mathbb{R}^{n}} \int_{\mathbb{R}^{n}} f(x)^{*} \hat{f}(p) \mathrm{e}^{\mathrm{i} p x} d^{n} p d^{n} x \\
& =\int_{\mathbb{R}^{n}}|f(x)|^{2} d^{n} x \tag{7.9}
\end{align*}
$$

for $f \in \mathcal{S}\left(\mathbb{R}^{n}\right)$. Thus, by Theorem 0.26 , we can extend $\mathcal{F}$ to $L^{2}\left(\mathbb{R}^{n}\right)$ by setting

$$
\begin{equation*}
\hat{f}(p)=\lim _{R \rightarrow \infty} \frac{1}{(2 \pi)^{n / 2}} \int_{|x| \leq R} \mathrm{e}^{-\mathrm{i} p x} f(x) d^{n} x, \tag{7.10}
\end{equation*}
$$

where the limit is to be understood in $L^{2}\left(\mathbb{R}^{n}\right)$ (Problem 7.5). If $f \in L^{1}\left(\mathbb{R}^{n}\right) \cap$ $L^{2}\left(\mathbb{R}^{n}\right)$, we can omit the limit (why?) and $\hat{f}$ is still given by (7.3).

Theorem 7.5. The Fourier transform $\mathcal{F}$ extends to a unitary operator $\mathcal{F}$ : $L^{2}\left(\mathbb{R}^{n}\right) \rightarrow L^{2}\left(\mathbb{R}^{n}\right)$. Its spectrum is given by

$$
\begin{equation*}
\sigma(\mathcal{F})=\left\{z \in \mathbb{C} \mid z^{4}=1\right\}=\{1,-1, \mathrm{i},-\mathrm{i}\} . \tag{7.11}
\end{equation*}
$$

Proof. As already noted, $\mathcal{F}$ extends uniquely to a bounded operator on $L^{2}\left(\mathbb{R}^{n}\right)$. Moreover, the same is true for $\mathcal{F}^{-1}$. Since Parseval's identity remains valid by continuity of the norm, this extension is a unitary operator.

It remains to compute the spectrum. In fact, if $\psi_{n}$ is a Weyl sequence, then $\left(\mathcal{F}^{2}+z^{2}\right)(\mathcal{F}+z)(\mathcal{F}-z) \psi_{n}=\left(\mathcal{F}^{4}-z^{4}\right) \psi_{n}=\left(1-z^{4}\right) \psi_{n} \rightarrow 0$ implies $z^{4}=1$. Hence $\sigma(\mathcal{F}) \subseteq\left\{z \in \mathbb{C} \mid z^{4}=1\right\}$. We defer the proof for equality to Section 8.3, where we will explicitly compute an orthonormal basis of eigenfunctions.

Lemma 7.1 also allows us to extend differentiation to a larger class. Let us introduce the Sobolev space

$$
\begin{equation*}
H^{r}\left(\mathbb{R}^{n}\right)=\left\{f \in L^{2}\left(\mathbb{R}^{n}\right) \|\left. p\right|^{r} \hat{f}(p) \in L^{2}\left(\mathbb{R}^{n}\right)\right\} \tag{7.12}
\end{equation*}
$$

Then, every function in $H^{r}\left(\mathbb{R}^{n}\right)$ has partial derivatives up to order $r$, which are defined via

$$
\begin{equation*}
\partial_{\alpha} f=\left((\mathrm{i} p)^{\alpha} \hat{f}(p)\right)^{\vee}, \quad f \in H^{r}\left(\mathbb{R}^{n}\right),|\alpha| \leq r . \tag{7.13}
\end{equation*}
$$

By Lemma 7.1 this definition coincides with the usual one for every $f \in$ $\mathcal{S}\left(\mathbb{R}^{n}\right)$ and we have

$$
\begin{align*}
\int_{\mathbb{R}^{n}} g(x)\left(\partial_{\alpha} f\right)(x) d^{n} x & =\left\langle g^{*},\left(\partial_{\alpha} f\right)\right\rangle=\left\langle\hat{g}(p)^{*},(\mathrm{i} p)^{\alpha} \hat{f}(p)\right\rangle \\
& =(-1)^{|\alpha|}\left\langle(\mathrm{i} p)^{\alpha} \hat{g}(p)^{*}, \hat{f}(p)\right\rangle=(-1)^{|\alpha|}\left\langle\partial_{\alpha} g^{*}, f\right\rangle \\
& =(-1)^{|\alpha|} \int_{\mathbb{R}^{n}}\left(\partial_{\alpha} g\right)(x) f(x) d^{n} x, \tag{7.14}
\end{align*}
$$

for $f, g \in H^{r}\left(\mathbb{R}^{n}\right)$. Furthermore, recall that a function $h \in L_{l o c}^{1}\left(\mathbb{R}^{n}\right)$ satisfying

$$
\begin{equation*}
\int_{\mathbb{R}^{n}} \varphi(x) h(x) d^{n} x=(-1)^{|\alpha|} \int_{\mathbb{R}^{n}}\left(\partial_{\alpha} \varphi\right)(x) f(x) d^{n} x, \quad \varphi \in C_{c}^{\infty}\left(\mathbb{R}^{n}\right) \tag{7.15}
\end{equation*}
$$

is also called the weak derivative or the derivative in the sense of distributions of $f$ (by Lemma 0.37 such a function is unique if it exists). Hence,
choosing $g=\varphi$ in (7.14), we see that $H^{r}\left(\mathbb{R}^{n}\right)$ is the set of all functions having partial derivatives (in the sense of distributions) up to order $r$, which are in $L^{2}\left(\mathbb{R}^{n}\right)$.

Finally, we note that on $L^{1}\left(\mathbb{R}^{n}\right)$ we have
Lemma 7.6 (Riemann-Lebesgue). Let $C_{\infty}\left(\mathbb{R}^{n}\right)$ denote the Banach space of all continuous functions $f: \mathbb{R}^{n} \rightarrow \mathbb{C}$ which vanish at $\infty$ equipped with the sup norm. Then the Fourier transform is a bounded injective map from $L^{1}\left(\mathbb{R}^{n}\right)$ into $C_{\infty}\left(\mathbb{R}^{n}\right)$ satisfying

$$
\begin{equation*}
\|\hat{f}\|_{\infty} \leq(2 \pi)^{-n / 2}\|f\|_{1} . \tag{7.16}
\end{equation*}
$$

Proof. Clearly we have $\hat{f} \in C_{\infty}\left(\mathbb{R}^{n}\right)$ if $f \in \mathcal{S}\left(\mathbb{R}^{n}\right)$. Moreover, since $\mathcal{S}\left(\mathbb{R}^{n}\right)$ is dense in $L^{1}\left(\mathbb{R}^{n}\right)$, the estimate

$$
\sup _{p}|\hat{f}(p)| \leq \frac{1}{(2 \pi)^{n / 2}} \sup _{p} \int_{\mathbb{R}^{n}}\left|\mathrm{e}^{-\mathrm{i} p x} f(x)\right| d^{n} x=\frac{1}{(2 \pi)^{n / 2}} \int_{\mathbb{R}^{n}}|f(x)| d^{n} x
$$

shows that the Fourier transform extends to a continuous map from $L^{1}\left(\mathbb{R}^{n}\right)$ into $C_{\infty}\left(\mathbb{R}^{n}\right)$.

To see that the Fourier transform is injective, suppose $\hat{f}=0$. Then Fubini implies

$$
0=\int_{\mathbb{R}^{n}} \varphi(x) \hat{f}(x) d^{n} x=\int_{\mathbb{R}^{n}} \hat{\varphi}(x) f(x) d^{n} x
$$

for every $\varphi \in \mathcal{S}\left(\mathbb{R}^{n}\right)$. Hence Lemma 0.37 implies $f=0$.
Note that $\mathcal{F}: L^{1}\left(\mathbb{R}^{n}\right) \rightarrow C_{\infty}\left(\mathbb{R}^{n}\right)$ is not onto (cf. Problem 7.7).
Another useful property is the convolution formula.

## Lemma 7.7. The convolution

$$
\begin{equation*}
(f * g)(x)=\int_{\mathbb{R}^{n}} f(y) g(x-y) d^{n} y=\int_{\mathbb{R}^{n}} f(x-y) g(y) d^{n} y \tag{7.17}
\end{equation*}
$$

of two functions $f, g \in L^{1}\left(\mathbb{R}^{n}\right)$ is again in $L^{1}\left(\mathbb{R}^{n}\right)$ and we have Young's inequality

$$
\begin{equation*}
\|f * g\|_{1} \leq\|f\|_{1}\|g\|_{1} . \tag{7.18}
\end{equation*}
$$

Moreover, its Fourier transform is given by

$$
\begin{equation*}
(f * g)^{\wedge}(p)=(2 \pi)^{n / 2} \hat{f}(p) \hat{g}(p) . \tag{7.19}
\end{equation*}
$$

Proof. The fact that $f * g$ is in $L^{1}$ together with Young's inequality follows by applying Fubini's theorem to $h(x, y)=f(x-y) g(y)$. For the last claim
we compute

$$
\begin{aligned}
(f * g)^{\wedge}(p) & =\frac{1}{(2 \pi)^{n / 2}} \int_{\mathbb{R}^{n}} \mathrm{e}^{-\mathrm{i} p x} \int_{\mathbb{R}^{n}} f(y) g(x-y) d^{n} y d^{n} x \\
& =\int_{\mathbb{R}^{n}} \mathrm{e}^{-\mathrm{i} p y} f(y) \frac{1}{(2 \pi)^{n / 2}} \int_{\mathbb{R}^{n}} \mathrm{e}^{-\mathrm{i} p(x-y)} g(x-y) d^{n} x d^{n} y \\
& =\int_{\mathbb{R}^{n}} \mathrm{e}^{-\mathrm{i} p y} f(y) \hat{g}(p) d^{n} y=(2 \pi)^{n / 2} \hat{f}(p) \hat{g}(p),
\end{aligned}
$$

where we have again used Fubini's theorem.
In other words, $L^{1}\left(\mathbb{R}^{n}\right)$ together with convolution as a product is a Banach algebra (without identity). For the case of convolution on $L^{2}\left(\mathbb{R}^{n}\right)$ see Problem 7.9.

Problem 7.1. Show that $\int_{\mathbb{R}} \exp \left(-x^{2} / 2\right) d x=\sqrt{2 \pi}$. (Hint: Square the integral and evaluate it using polar coordinates.)

Problem 7.2. Compute the Fourier transform of the following functions $f: \mathbb{R} \rightarrow \mathbb{C}$ :
(i) $f(x)=\chi_{(-1,1)}(x)$.
(ii) $f(p)=\frac{1}{p^{2}+k^{2}}, \quad \operatorname{Re}(k)>0$.

Problem 7.3. Suppose $f(x) \in L^{1}(\mathbb{R})$ and $g(x)=-\mathrm{i} x f(x) \in L^{1}(\mathbb{R})$. Then $\hat{f}$ is differentiable and $\hat{f}^{\prime}=\hat{g}$.

Problem 7.4. A function $f: \mathbb{R}^{n} \rightarrow \mathbb{C}$ is called spherically symmetric if it is invariant under rotations; that is, $f(O x)=f(x)$ for all $O \in S O\left(\mathbb{R}^{n}\right)$ (equivalently, $f$ depends only on the distance to the origin $|x|$ ). Show that the Fourier transform of a spherically symmetric function is again spherically symmetric.

Problem 7.5. Show (7.10). (Hint: First suppose $f$ has compact support. Then there is a sequence of functions $f_{n} \in C_{c}^{\infty}\left(\mathbb{R}^{n}\right)$ converging to $f$ in $L^{2}$. The support of these functions can be chosen inside a fixed set and hence this sequence also converges to $f$ in $L^{1}$. Thus (7.10) follows for $f \in L^{2}$ with compact support. To remove this restriction, use that the projection onto a ball with radius $R$ converges strongly to the identity as $R \rightarrow \infty$.)

Problem 7.6. Show that $C_{\infty}\left(\mathbb{R}^{n}\right)$ is indeed a Banach space. Show that $\mathcal{S}\left(\mathbb{R}^{n}\right)$ is dense.
Problem 7.7. Show that $\mathcal{F}: L^{1}\left(\mathbb{R}^{n}\right) \rightarrow C_{\infty}\left(\mathbb{R}^{n}\right)$ is not onto as follows:
(i) The range of $\mathcal{F}$ is dense.
(ii) $\mathcal{F}$ is onto if and only if it has a bounded inverse.
(iii) $\mathcal{F}$ has no bounded inverse.
(Hint for (iii): Suppose $\varphi$ is smooth with compact support in $(0,1)$ and set $f_{m}(x)=\sum_{k=1}^{m} \mathrm{e}^{\mathrm{i} k x} \varphi(x-k)$. Then $\left\|f_{m}\right\|_{1}=m\|\varphi\|_{1}$ and $\left\|\hat{f}_{m}\right\|_{\infty} \leq$ const since $\varphi \in \mathcal{S}(\mathbb{R})$ and hence $\left.\varphi(p) \leq \operatorname{const}(1+|p|)^{-2}\right)$.

Problem 7.8. Show that the convolution of two $\mathcal{S}\left(\mathbb{R}^{n}\right)$ functions is in $\mathcal{S}\left(\mathbb{R}^{n}\right)$.

Problem 7.9. Show that the convolution of two $L^{2}\left(\mathbb{R}^{n}\right)$ functions is in $C_{\infty}\left(\mathbb{R}^{n}\right)$ and we have $\|f * g\|_{\infty} \leq\|f\|_{2}\|g\|_{2}$.

Problem 7.10 (Wiener). Suppose $f \in L^{2}\left(\mathbb{R}^{n}\right)$. Then the set $\{f(x+a) \mid a \in$ $\left.\mathbb{R}^{n}\right\}$ is total in $L^{2}\left(\mathbb{R}^{n}\right)$ if and only if $\hat{f}(p) \neq 0$ a.e. (Hint: Use Lemma 7.2 and the fact that a subspace is total if and only if its orthogonal complement is zero.)

Problem 7.11. Suppose $f(x) \mathrm{e}^{k|x|} \in L^{1}(\mathbb{R})$ for some $k>0$. Then $\hat{f}(p)$ has an analytic extension to the strip $|\operatorname{Im}(p)|<k$.

### 7.2. The free Schrödinger operator

In Section 2.1 we have seen that the Hilbert space corresponding to one particle in $\mathbb{R}^{3}$ is $L^{2}\left(\mathbb{R}^{3}\right)$. More generally, the Hilbert space for $N$ particles in $\mathbb{R}^{d}$ is $L^{2}\left(\mathbb{R}^{n}\right), n=N d$. The corresponding nonrelativistic Hamilton operator, if the particles do not interact, is given by

$$
\begin{equation*}
H_{0}=-\Delta, \tag{7.20}
\end{equation*}
$$

where $\Delta$ is the Laplace operator

$$
\begin{equation*}
\Delta=\sum_{j=1}^{n} \frac{\partial^{2}}{\partial x_{j}^{2}} . \tag{7.21}
\end{equation*}
$$

Here we have chosen units such that all relevant physical constants disappear; that is, $\hbar=1$ and the mass of the particles is equal to $m=\frac{1}{2}$. Be aware that some authors prefer to use $m=1$; that is, $H_{0}=-\frac{1}{2} \Delta$.

Our first task is to find a good domain such that $H_{0}$ is a self-adjoint operator.

By Lemma 7.1 we have that

$$
\begin{equation*}
-\Delta \psi(x)=\left(p^{2} \hat{\psi}(p)\right)^{\vee}(x), \quad \psi \in H^{2}\left(\mathbb{R}^{n}\right) \tag{7.22}
\end{equation*}
$$

and hence the operator

$$
\begin{equation*}
H_{0} \psi=-\Delta \psi, \quad \mathfrak{D}\left(H_{0}\right)=H^{2}\left(\mathbb{R}^{n}\right) \tag{7.23}
\end{equation*}
$$

is unitarily equivalent to the maximally defined multiplication operator

$$
\begin{equation*}
\left(\mathcal{F} H_{0} \mathcal{F}^{-1}\right) \varphi(p)=p^{2} \varphi(p), \quad \mathfrak{D}\left(p^{2}\right)=\left\{\varphi \in L^{2}\left(\mathbb{R}^{n}\right) \mid p^{2} \varphi(p) \in L^{2}\left(\mathbb{R}^{n}\right)\right\} \tag{7.24}
\end{equation*}
$$

Theorem 7.8. The free Schrödinger operator $H_{0}$ is self-adjoint and its spectrum is characterized by

$$
\begin{equation*}
\sigma\left(H_{0}\right)=\sigma_{a c}\left(H_{0}\right)=[0, \infty), \quad \sigma_{s c}\left(H_{0}\right)=\sigma_{p p}\left(H_{0}\right)=\emptyset . \tag{7.25}
\end{equation*}
$$

Proof. It suffices to show that $d \mu_{\psi}$ is purely absolutely continuous for every $\psi$. First observe that

$$
\left\langle\psi, R_{H_{0}}(z) \psi\right\rangle=\left\langle\hat{\psi}, R_{p^{2}}(z) \hat{\psi}\right\rangle=\int_{\mathbb{R}^{n}} \frac{|\hat{\psi}(p)|^{2}}{p^{2}-z} d^{n} p=\int_{\mathbb{R}} \frac{1}{r^{2}-z} d \tilde{\mu}_{\psi}(r),
$$

where

$$
d \tilde{\mu}_{\psi}(r)=\chi_{[0, \infty)}(r) r^{n-1}\left(\int_{S^{n-1}}|\hat{\psi}(r \omega)|^{2} d^{n-1} \omega\right) d r
$$

Hence, after a change of coordinates, we have

$$
\left\langle\psi, R_{H_{0}}(z) \psi\right\rangle=\int_{\mathbb{R}} \frac{1}{\lambda-z} d \mu_{\psi}(\lambda),
$$

where

$$
d \mu_{\psi}(\lambda)=\frac{1}{2} \chi_{[0, \infty)}(\lambda) \lambda^{n / 2-1}\left(\int_{S^{n-1}}|\hat{\psi}(\sqrt{\lambda} \omega)|^{2} d^{n-1} \omega\right) d \lambda,
$$

proving the claim.
Finally, we note that the compactly supported smooth functions are a core for $H_{0}$.

Lemma 7.9. The set $C_{c}^{\infty}\left(\mathbb{R}^{n}\right)=\left\{f \in \mathcal{S}\left(\mathbb{R}^{n}\right) \mid \operatorname{supp}(f)\right.$ is compact $\}$ is a core for $H_{0}$.

Proof. It is not hard to see that $\mathcal{S}\left(\mathbb{R}^{n}\right)$ is a core (Problem 7.12) and hence it suffices to show that the closure of $\left.H_{0}\right|_{C_{c}^{\infty}\left(\mathbb{R}^{n}\right)}$ contains $\left.H_{0}\right|_{\mathcal{S}\left(\mathbb{R}^{n}\right)}$. To see this, let $\varphi(x) \in C_{c}^{\infty}\left(\mathbb{R}^{n}\right)$ which is one for $|x| \leq 1$ and vanishes for $|x| \geq 2$. Set $\varphi_{n}(x)=\varphi\left(\frac{1}{n} x\right)$. Then $\psi_{n}(x)=\varphi_{n}(x) \psi(x)$ is in $C_{c}^{\infty}\left(\mathbb{R}^{n}\right)$ for every $\psi \in \mathcal{S}\left(\mathbb{R}^{n}\right)$ and $\psi_{n} \rightarrow \psi$, respectively, $\Delta \psi_{n} \rightarrow \Delta \psi$.

Note also that the quadratic form of $H_{0}$ is given by

$$
\begin{equation*}
q_{H_{0}}(\psi)=\sum_{j=1}^{n} \int_{\mathbb{R}^{n}}\left|\partial_{j} \psi(x)\right|^{2} d^{n} x, \quad \psi \in \mathfrak{Q}\left(H_{0}\right)=H^{1}\left(\mathbb{R}^{n}\right) \tag{7.26}
\end{equation*}
$$

Problem 7.12. Show that $\mathcal{S}\left(\mathbb{R}^{n}\right)$ is a core for $H_{0}$. (Hint: Show that the closure of $\left.H_{0}\right|_{\mathcal{S}\left(\mathbb{R}^{n}\right)}$ contains $H_{0}$.)
Problem 7.13. Show that $\{\psi \in \mathcal{S}(\mathbb{R}) \mid \psi(0)=0\}$ is dense but not a core for $H_{0}=-\frac{d^{2}}{d x^{2}}$.

### 7.3. The time evolution in the free case

Now let us look at the time evolution. We have

$$
\begin{equation*}
\mathrm{e}^{-\mathrm{i} t H_{0}} \psi(x)=\mathcal{F}^{-1} \mathrm{e}^{-\mathrm{i} t p^{2}} \hat{\psi}(p) . \tag{7.27}
\end{equation*}
$$

The right-hand side is a product and hence our operator should be expressible as an integral operator via the convolution formula. However, since $\mathrm{e}^{-\mathrm{i} t p^{2}}$ is not in $L^{2}$, a more careful analysis is needed.

Consider

$$
\begin{equation*}
f_{\varepsilon}\left(p^{2}\right)=\mathrm{e}^{-(i t+\varepsilon) p^{2}}, \quad \varepsilon>0 . \tag{7.28}
\end{equation*}
$$

Then $f_{\varepsilon}\left(H_{0}\right) \psi \rightarrow \mathrm{e}^{-\mathrm{i} t H_{0}} \psi$ by Theorem 3.1. Moreover, by Lemma 7.3 and the convolution formula we have

$$
\begin{equation*}
f_{\varepsilon}\left(H_{0}\right) \psi(x)=\frac{1}{(4 \pi(\mathrm{i} t+\varepsilon))^{n / 2}} \int_{\mathbb{R}^{n}} \mathrm{e}^{-\frac{|x-y|^{2}}{4(\mathrm{i} t+\varepsilon)}} \psi(y) d^{n} y \tag{7.29}
\end{equation*}
$$

and hence

$$
\begin{equation*}
\mathrm{e}^{-\mathrm{i} t H_{0}} \psi(x)=\frac{1}{(4 \pi \mathrm{i} t)^{n / 2}} \int_{\mathbb{R}^{n}} \mathrm{e}^{\mathrm{i} \frac{|x-y|^{2}}{4 t}} \psi(y) d^{n} y \tag{7.30}
\end{equation*}
$$

for $t \neq 0$ and $\psi \in L^{1} \cap L^{2}$. For general $\psi \in L^{2}$ the integral has to be understood as a limit.

Using this explicit form, it is not hard to draw some immediate consequences. For example, if $\psi \in L^{2}\left(\mathbb{R}^{n}\right) \cap L^{1}\left(\mathbb{R}^{n}\right)$, then $\psi(t) \in C\left(\mathbb{R}^{n}\right)$ for $t \neq 0$ (use dominated convergence and continuity of the exponential) and satisfies

$$
\begin{equation*}
\|\psi(t)\|_{\infty} \leq \frac{1}{|4 \pi t|^{n / 2}}\|\psi(0)\|_{1} . \tag{7.31}
\end{equation*}
$$

Thus we have spreading of wave functions in this case. Moreover, it is even possible to determine the asymptotic form of the wave function for large $t$ as follows. Observe

$$
\begin{align*}
\mathrm{e}^{-\mathrm{i} t H_{0}} \psi(x) & =\frac{\mathrm{e}^{\mathrm{i} \frac{x^{2}}{4 t}}}{(4 \pi \mathrm{i} t)^{n / 2}} \int_{\mathbb{R}^{n}} \mathrm{e}^{\mathrm{i} \frac{y^{2}}{4 t}} \psi(y) \mathrm{e}^{\mathrm{i} \frac{x y}{2 t}} d^{n} y \\
& =\left(\frac{1}{2 \mathrm{i} t}\right)^{n / 2} \mathrm{e}^{\mathrm{i} \frac{x^{2}}{4 t}}\left(\mathrm{e}^{\mathrm{i} \frac{y^{2}}{4 t}} \psi(y)\right)^{\wedge}\left(\frac{x}{2 t}\right) . \tag{7.32}
\end{align*}
$$

Moreover, since $\exp \left(\mathrm{i} \frac{y^{2}}{4 t}\right) \psi(y) \rightarrow \psi(y)$ in $L^{2}$ as $|t| \rightarrow \infty$ (dominated convergence), we obtain
Lemma 7.10. For any $\psi \in L^{2}\left(\mathbb{R}^{n}\right)$ we have

$$
\begin{equation*}
\mathrm{e}^{-\mathrm{i} t H_{0}} \psi(x)-\left(\frac{1}{2 \mathrm{i} t}\right)^{n / 2} \mathrm{e}^{\mathrm{i} \frac{x^{2}}{4 t}} \hat{\psi}\left(\frac{x}{2 t}\right) \rightarrow 0 \tag{7.33}
\end{equation*}
$$

in $L^{2}$ as $|t| \rightarrow \infty$.

Note that this result is not too surprising from a physical point of view. In fact, if a classical particle starts at a point $x(0)=x_{0}$ with velocity $v=2 p$ (recall that we use units where the mass is $m=\frac{1}{2}$ ), then we will find it at $x=x_{0}+2 p t$ at time $t$. Dividing by $2 t$, we get $\frac{x}{2 t}=p+\frac{x_{0}}{2 t} \approx p$ for large $t$. Hence the probability distribution for finding a particle at a point $x$ at time $t$ should approach the probability distribution for the momentum at $p=\frac{x}{2 t}$; that is, $|\psi(x, t)|^{2} d^{n} x=\left|\psi\left(\frac{x}{2 t}\right)\right|^{2} \frac{d^{n} x}{(2 t)^{n}}$. This could also be stated as follows: The probability of finding the particle in a region $\Omega \subseteq \mathbb{R}^{n}$ is asymptotically for $|t| \rightarrow \infty$ equal to the probability of finding the momentum of the particle in $\frac{1}{2 t} \Omega$.

Next we want to apply the RAGE theorem in order to show that for any initial condition, a particle will escape to infinity.

Lemma 7.11. Let $g(x)$ be the multiplication operator by $g$ and let $f(p)$ be the operator given by $f(p) \psi(x)=\mathcal{F}^{-1}(f(p) \hat{\psi}(p))(x)$. Denote by $L_{\infty}^{\infty}\left(\mathbb{R}^{n}\right)$ the bounded Borel functions which vanish at infinity. Then

$$
\begin{equation*}
f(p) g(x) \quad \text { and } \quad g(x) f(p) \tag{7.34}
\end{equation*}
$$

are compact if $f, g \in L_{\infty}^{\infty}\left(\mathbb{R}^{n}\right)$ and (extend to) Hilbert-Schmidt operators if $f, g \in L^{2}\left(\mathbb{R}^{n}\right)$.

Proof. By symmetry it suffices to consider $g(x) f(p)$. Let $f, g \in L^{2}$. Then

$$
g(x) f(p) \psi(x)=\frac{1}{(2 \pi)^{n / 2}} \int_{\mathbb{R}^{n}} g(x) \check{f}(x-y) \psi(y) d^{n} y
$$

shows that $g(x) f(p)$ is Hilbert-Schmidt since $g(x) \check{f}(x-y) \in L^{2}\left(\mathbb{R}^{n} \times \mathbb{R}^{n}\right)$.
If $f, g$ are bounded, then the functions $f_{R}(p)=\chi_{\left\{p \mid p^{2} \leq R\right\}}(p) f(p)$ and $g_{R}(x)=\chi_{\left\{x \mid x^{2} \leq R\right\}}(x) g(x)$ are in $L^{2}$. Thus $g_{R}(x) f_{R}(p)$ is compact and by

$$
\left\|g(x) f(p)-g_{R}(x) f_{R}(p)\right\| \leq\|g\|_{\infty}\left\|f-f_{R}\right\|_{\infty}+\left\|g-g_{R}\right\|_{\infty}\left\|f_{R}\right\|_{\infty}
$$

it tends to $g(x) f(p)$ in norm since $f, g$ vanish at infinity.
In particular, this lemma implies that

$$
\begin{equation*}
\chi_{\Omega}\left(H_{0}+\mathrm{i}\right)^{-1} \tag{7.35}
\end{equation*}
$$

is compact if $\Omega \subseteq \mathbb{R}^{n}$ is bounded and hence

$$
\begin{equation*}
\lim _{t \rightarrow \infty}\left\|\chi_{\Omega} \mathrm{e}^{-\mathrm{i} t H_{0}} \psi\right\|^{2}=0 \tag{7.36}
\end{equation*}
$$

for any $\psi \in L^{2}\left(\mathbb{R}^{n}\right)$ and any bounded subset $\Omega$ of $\mathbb{R}^{n}$. In other words, the particle will eventually escape to infinity since the probability of finding the particle in any bounded set tends to zero. (If $\psi \in L^{1}\left(\mathbb{R}^{n}\right)$, this of course also follows from (7.31).)

### 7.4. The resolvent and Green's function

Now let us compute the resolvent of $H_{0}$. We will try to use an approach similar to that for the time evolution in the previous section. However, since it is highly nontrivial to compute the inverse Fourier transform of $\exp \left(-\varepsilon p^{2}\right)\left(p^{2}-z\right)^{-1}$ directly, we will use a small ruse.

Note that

$$
\begin{equation*}
R_{H_{0}}(z)=\int_{0}^{\infty} \mathrm{e}^{z t} \mathrm{e}^{-t H_{0}} d t, \quad \operatorname{Re}(z)<0 \tag{7.37}
\end{equation*}
$$

by Lemma 4.1. Moreover,

$$
\begin{equation*}
\mathrm{e}^{-t H_{0}} \psi(x)=\frac{1}{(4 \pi t)^{n / 2}} \int_{\mathbb{R}^{n}} \mathrm{e}^{-\frac{|x-y|^{2}}{4 t}} \psi(y) d^{n} y, \quad t>0, \tag{7.38}
\end{equation*}
$$

by the same analysis as in the previous section. Hence, by Fubini, we have

$$
\begin{equation*}
R_{H_{0}}(z) \psi(x)=\int_{\mathbb{R}^{n}} G_{0}(z,|x-y|) \psi(y) d^{n} y \tag{7.39}
\end{equation*}
$$

where

$$
\begin{equation*}
G_{0}(z, r)=\int_{0}^{\infty} \frac{1}{(4 \pi t)^{n / 2}} \mathrm{e}^{-\frac{r^{2}}{4 t}+z t} d t, \quad r>0, \operatorname{Re}(z)<0 \tag{7.40}
\end{equation*}
$$

The function $G_{0}(z, r)$ is called Green's function of $H_{0}$. The integral can be evaluated in terms of modified Bessel functions of the second kind as follows: First of all it suffices to consider $z<0$ since the remaining values will follow by analytic continuation. Then, making the substitution $t=\frac{r}{2 \sqrt{-z}} \mathrm{e}^{s}$, we obtain

$$
\begin{align*}
\int_{0}^{\infty} \frac{1}{(4 \pi t)^{n / 2}} \mathrm{e}^{-\frac{r^{2}}{4 t}+z t} d t & =\frac{1}{4 \pi}\left(\frac{\sqrt{-z}}{2 \pi r}\right)^{\frac{n}{2}-1} \int_{-\infty}^{\infty} \mathrm{e}^{-\nu s} \mathrm{e}^{-x \cosh (s)} d s \\
& =\frac{1}{2 \pi}\left(\frac{\sqrt{-z}}{2 \pi r}\right)^{\frac{n}{2}-1} \int_{0}^{\infty} \cosh (-\nu s) \mathrm{e}^{-x \cosh (s)} d s \tag{7.41}
\end{align*}
$$

where we have abbreviated $x=\sqrt{-z} r$ and $\nu=\frac{n}{2}-1$. But the last integral is given by the modified Bessel function $K_{\nu}(x)$ (see [1, (9.6.24)]) and thus

$$
\begin{equation*}
G_{0}(z, r)=\frac{1}{2 \pi}\left(\frac{\sqrt{-z}}{2 \pi r}\right)^{\frac{n}{2}-1} K_{\frac{n}{2}-1}(\sqrt{-z r}) \tag{7.42}
\end{equation*}
$$

Note $K_{\nu}(x)=K_{-\nu}(x)$ and $K_{\nu}(x)>0$ for $\nu, x \in \mathbb{R}$. The functions $K_{\nu}(x)$ satisfy the differential equation (see [1, (9.6.1)])

$$
\begin{equation*}
\left(\frac{d^{2}}{d x^{2}}+\frac{1}{x} \frac{d}{d x}-1-\frac{\nu^{2}}{x^{2}}\right) K_{\nu}(x)=0 \tag{7.43}
\end{equation*}
$$

and have the asymptotics (see $[\mathbf{1},(9.6 .8)$ and (9.6.9)])

$$
K_{\nu}(x)= \begin{cases}\frac{\Gamma(\nu)}{2}\left(\frac{x}{2}\right)^{-\nu}+O\left(x^{-\nu+2}\right), & \nu>0,  \tag{7.44}\\ -\log \left(\frac{x}{2}\right)+O(1), & \nu=0,\end{cases}
$$

for $|x| \rightarrow 0$ and (see [1, (9.7.2)])

$$
\begin{equation*}
K_{\nu}(x)=\sqrt{\frac{\pi}{2 x}} \mathrm{e}^{-x}\left(1+O\left(x^{-1}\right)\right) \tag{7.45}
\end{equation*}
$$

for $|x| \rightarrow \infty$. For more information see for example [1] or [59]. In particular, $G_{0}(z, r)$ has an analytic continuation for $z \in \mathbb{C} \backslash[0, \infty)=\rho\left(H_{0}\right)$. Hence we can define the right-hand side of (7.39) for all $z \in \rho\left(H_{0}\right)$ such that

$$
\begin{equation*}
\int_{\mathbb{R}^{n}} \int_{\mathbb{R}^{n}} \varphi(x) G_{0}(z,|x-y|) \psi(y) d^{n} y d^{n} x \tag{7.46}
\end{equation*}
$$

is analytic for $z \in \rho\left(H_{0}\right)$ and $\varphi, \psi \in \mathcal{S}\left(\mathbb{R}^{n}\right)$ (by Morera's theorem). Since it is equal to $\left\langle\varphi, R_{H_{0}}(z) \psi\right\rangle$ for $\operatorname{Re}(z)<0$, it is equal to this function for all $z \in \rho\left(H_{0}\right)$, since both functions are analytic in this domain. In particular, (7.39) holds for all $z \in \rho\left(H_{0}\right)$.

If $n$ is odd, we have the case of spherical Bessel functions which can be expressed in terms of elementary functions. For example, we have

$$
\begin{equation*}
G_{0}(z, r)=\frac{1}{2 \sqrt{-z}} \mathrm{e}^{-\sqrt{-z} r}, \quad n=1, \tag{7.47}
\end{equation*}
$$

and

$$
\begin{equation*}
G_{0}(z, r)=\frac{1}{4 \pi r} \mathrm{e}^{-\sqrt{-z} r}, \quad n=3 . \tag{7.48}
\end{equation*}
$$

Problem 7.14. Verify (7.39) directly in the case $n=1$.

# Chapter 8 

## Algebraic methods

### 8.1. Position and momentum

Apart from the Hamiltonian $H_{0}$, which corresponds to the kinetic energy, there are several other important observables associated with a single particle in three dimensions. Using the commutation relation between these observables, many important consequences about these observables can be derived.

First consider the one-parameter unitary group

$$
\begin{equation*}
\left(U_{j}(t) \psi\right)(x)=\mathrm{e}^{-\mathrm{i} t x_{j}} \psi(x), \quad 1 \leq j \leq 3 \tag{8.1}
\end{equation*}
$$

For $\psi \in \mathcal{S}\left(\mathbb{R}^{3}\right)$ we compute

$$
\begin{equation*}
\lim _{t \rightarrow 0} \mathrm{i} \frac{\mathrm{e}^{-\mathrm{i} t x_{j}} \psi(x)-\psi(x)}{t}=x_{j} \psi(x) \tag{8.2}
\end{equation*}
$$

and hence the generator is the multiplication operator by the $j$ 'th coordinate function. By Corollary 5.3 it is essentially self-adjoint on $\psi \in \mathcal{S}\left(\mathbb{R}^{3}\right)$. It is customary to combine all three operators into one vector-valued operator $x$, which is known as the position operator. Moreover, it is not hard to see that the spectrum of $x_{j}$ is purely absolutely continuous and given by $\sigma\left(x_{j}\right)=\mathbb{R}$. In fact, let $\varphi(x)$ be an orthonormal basis for $L^{2}(\mathbb{R})$. Then $\varphi_{i}\left(x_{1}\right) \varphi_{j}\left(x_{2}\right) \varphi_{k}\left(x_{3}\right)$ is an orthonormal basis for $L^{2}\left(\mathbb{R}^{3}\right)$ and $x_{1}$ can be written as an orthogonal sum of operators restricted to the subspaces spanned by $\varphi_{j}\left(x_{2}\right) \varphi_{k}\left(x_{3}\right)$. Each subspace is unitarily equivalent to $L^{2}(\mathbb{R})$ and $x_{1}$ is given by multiplication with the identity. Hence the claim follows (or use Theorem 4.14).

Next, consider the one-parameter unitary group of translations

$$
\begin{equation*}
\left(U_{j}(t) \psi\right)(x)=\psi\left(x-t e_{j}\right), \quad 1 \leq j \leq 3 \tag{8.3}
\end{equation*}
$$

where $e_{j}$ is the unit vector in the $j^{\prime}$ th coordinate direction. For $\psi \in \mathcal{S}\left(\mathbb{R}^{3}\right)$ we compute

$$
\begin{equation*}
\lim _{t \rightarrow 0} \mathrm{i} \frac{\psi\left(x-t e_{j}\right)-\psi(x)}{t}=\frac{1}{\mathrm{i}} \frac{\partial}{\partial x_{j}} \psi(x) \tag{8.4}
\end{equation*}
$$

and hence the generator is $p_{j}=\frac{1}{\mathrm{i}} \frac{\partial}{\partial x_{j}}$. Again it is essentially self-adjoint on $\psi \in \mathcal{S}\left(\mathbb{R}^{3}\right)$. Moreover, since it is unitarily equivalent to $x_{j}$ by virtue of the Fourier transform, we conclude that the spectrum of $p_{j}$ is again purely absolutely continuous and given by $\sigma\left(p_{j}\right)=\mathbb{R}$. The operator $p$ is known as the momentum operator. Note that since

$$
\begin{equation*}
\left[H_{0}, p_{j}\right] \psi(x)=0, \quad \psi \in \mathcal{S}\left(\mathbb{R}^{3}\right) \tag{8.5}
\end{equation*}
$$

we have

$$
\begin{equation*}
\frac{d}{d t}\left\langle\psi(t), p_{j} \psi(t)\right\rangle=0, \quad \psi(t)=\mathrm{e}^{-\mathrm{i} t H_{0}} \psi(0) \in \mathcal{S}\left(\mathbb{R}^{3}\right) ; \tag{8.6}
\end{equation*}
$$

that is, the momentum is a conserved quantity for the free motion. More generally we have

Theorem 8.1 (Noether). Suppose $A$ is a self-adjoint operator which commutes with a self-adjoint operator $H$. Then $\mathfrak{D}(A)$ is invariant under $\mathrm{e}^{-\mathrm{i} t H}$, that is, $\mathrm{e}^{-\mathrm{i} t H} \mathfrak{D}(A)=\mathfrak{D}(A)$, and $A$ is a conserved quantity, that is,

$$
\begin{equation*}
\langle\psi(t), A \psi(t)\rangle=\langle\psi(0), A \psi(0)\rangle, \quad \psi(t)=\mathrm{e}^{-\mathrm{i} t H} \psi(0) \in \mathfrak{D}(A) . \tag{8.7}
\end{equation*}
$$

Proof. By the second part of Lemma 4.5 (with $f(\lambda)=\lambda$ and $B=\mathrm{e}^{-\mathrm{i} t H}$ ) we see $\mathfrak{D}(A)=\mathfrak{D}\left(\mathrm{e}^{-\mathrm{i} t H} A\right) \subseteq \mathfrak{D}\left(A \mathrm{e}^{-\mathrm{i} t H}\right)=\left\{\psi \mid \mathrm{e}^{-\mathrm{i} t H} \psi \in \mathfrak{D}(A)\right\}$ which implies $\mathrm{e}^{-\mathrm{i} t H} \mathfrak{D}(A) \subseteq \mathfrak{D}(A)$, and $\left[\mathrm{e}^{-\mathrm{i} t H}, A\right] \psi=0$ for $\psi \in \mathfrak{D}(A)$.

Similarly one has

$$
\begin{equation*}
\mathrm{i}\left[p_{j}, x_{k}\right] \psi(x)=\delta_{j k} \psi(x), \quad \psi \in \mathcal{S}\left(\mathbb{R}^{3}\right) \tag{8.8}
\end{equation*}
$$

which is known as the Weyl relations. In terms of the corresponding unitary groups they read

$$
\begin{equation*}
\mathrm{e}^{-\mathrm{i} s p_{j}} \mathrm{e}^{-\mathrm{i} t x_{k}}=\mathrm{e}^{\mathrm{i} s t \delta_{j k}} \mathrm{e}^{-\mathrm{i} t x_{j}} \mathrm{e}^{-\mathrm{i} s p_{k}} . \tag{8.9}
\end{equation*}
$$

The Weyl relations also imply that the mean-square deviation of position and momentum cannot be made arbitrarily small simultaneously:

Theorem 8.2 (Heisenberg Uncertainty Principle). Suppose $A$ and $B$ are two symmetric operators. Then for any $\psi \in \mathfrak{D}(A B) \cap \mathfrak{D}(B A)$ we have

$$
\begin{equation*}
\Delta_{\psi}(A) \Delta_{\psi}(B) \geq \frac{1}{2}\left|\mathbb{E}_{\psi}([A, B])\right| \tag{8.10}
\end{equation*}
$$

with equality if

$$
\begin{equation*}
\left(B-\mathbb{E}_{\psi}(B)\right) \psi=\mathrm{i} \lambda\left(A-\mathbb{E}_{\psi}(A)\right) \psi, \quad \lambda \in \mathbb{R} \backslash\{0\}, \tag{8.11}
\end{equation*}
$$

or if $\psi$ is an eigenstate of $A$ or $B$.

Proof. Let us fix $\psi \in \mathfrak{D}(A B) \cap \mathfrak{D}(B A)$ and abbreviate

$$
\hat{A}=A-\mathbb{E}_{\psi}(A), \quad \hat{B}=B-\mathbb{E}_{\psi}(B) .
$$

Then $\Delta_{\psi}(A)=\|\hat{A} \psi\|, \Delta_{\psi}(B)=\|\hat{B} \psi\|$ and hence by Cauchy-Schwarz

$$
|\langle\hat{A} \psi, \hat{B} \psi\rangle| \leq \Delta_{\psi}(A) \Delta_{\psi}(B) .
$$

Now note that

$$
\hat{A} \hat{B}=\frac{1}{2}\{\hat{A}, \hat{B}\}+\frac{1}{2}[A, B], \quad\{\hat{A}, \hat{B}\}=\hat{A} \hat{B}+\hat{B} \hat{A}
$$

where $\{\hat{A}, \hat{B}\}$ and $\mathrm{i}[A, B]$ are symmetric. So

$$
|\langle\hat{A} \psi, \hat{B} \psi\rangle|^{2}=|\langle\psi, \hat{A} \hat{B} \psi\rangle|^{2}=\frac{1}{2}|\langle\psi,\{\hat{A}, \hat{B}\} \psi\rangle|^{2}+\frac{1}{2}|\langle\psi,[A, B] \psi\rangle|^{2}
$$

which proves (8.10).
To have equality if $\psi$ is not an eigenstate, we need $\hat{B} \psi=z \hat{A} \psi$ for equality in Cauchy-Schwarz and $\langle\psi,\{\hat{A}, \hat{B}\} \psi\rangle=0$. Inserting the first into the second requirement gives $0=\left(z-z^{*}\right)\|\hat{A} \psi\|^{2}$ and shows $\operatorname{Re}(z)=0$.

In the case of position and momentum we have $(\|\psi\|=1)$

$$
\begin{equation*}
\Delta_{\psi}\left(p_{j}\right) \Delta_{\psi}\left(x_{k}\right) \geq \frac{\delta_{j k}}{2} \tag{8.12}
\end{equation*}
$$

and the minimum is attained for the Gaussian wave packets

$$
\begin{equation*}
\psi(x)=\left(\frac{\lambda}{\pi}\right)^{n / 4} \mathrm{e}^{-\frac{\lambda}{2}\left|x-x_{0}\right|^{2}-\mathrm{i} p_{0} x} \tag{8.13}
\end{equation*}
$$

which satisfy $\mathbb{E}_{\psi}(x)=x_{0}$ and $\mathbb{E}_{\psi}(p)=p_{0}$, respectively, $\Delta_{\psi}\left(p_{j}\right)^{2}=\frac{\lambda}{2}$ and $\Delta_{\psi}\left(x_{k}\right)^{2}=\frac{1}{2 \lambda}$.
Problem 8.1. Check that (8.13) realizes the minimum.

### 8.2. Angular momentum

Now consider the one-parameter unitary group of rotations

$$
\begin{equation*}
\left(U_{j}(t) \psi\right)(x)=\psi\left(M_{j}(t) x\right), \quad 1 \leq j \leq 3, \tag{8.14}
\end{equation*}
$$

where $M_{j}(t)$ is the matrix of rotation around $e_{j}$ by an angle of $t$. For $\psi \in \mathcal{S}\left(\mathbb{R}^{3}\right)$ we compute

$$
\begin{equation*}
\lim _{t \rightarrow 0} \mathrm{i} \frac{\psi\left(M_{i}(t) x\right)-\psi(x)}{t}=\sum_{j, k=1}^{3} \varepsilon_{i j k} x_{j} p_{k} \psi(x), \tag{8.15}
\end{equation*}
$$

where

$$
\varepsilon_{i j k}= \begin{cases}1 & \text { if } i j k \text { is an even permutation of } 123,  \tag{8.16}\\ -1 & \text { if } i j k \text { is an odd permutation of } 123, \\ 0 & \text { otherwise } .\end{cases}
$$

Again one combines the three components into one vector-valued operator $L=x \wedge p$, which is known as the angular momentum operator. Since $\mathrm{e}^{\mathrm{i} 2 \pi L_{j}}=\mathbb{I}$, we see that the spectrum is a subset of $\mathbb{Z}$. In particular, the continuous spectrum is empty. We will show below that we have $\sigma\left(L_{j}\right)=\mathbb{Z}$. Note that since

$$
\begin{equation*}
\left[H_{0}, L_{j}\right] \psi(x)=0, \quad \psi \in \mathcal{S}\left(\mathbb{R}^{3}\right), \tag{8.17}
\end{equation*}
$$

we again have

$$
\begin{equation*}
\frac{d}{d t}\left\langle\psi(t), L_{j} \psi(t)\right\rangle=0, \quad \psi(t)=\mathrm{e}^{-\mathrm{i} t H_{0}} \psi(0) \in \mathcal{S}\left(\mathbb{R}^{3}\right) ; \tag{8.18}
\end{equation*}
$$

that is, the angular momentum is a conserved quantity for the free motion as well.

Moreover, we even have

$$
\begin{equation*}
\left[L_{i}, K_{j}\right] \psi(x)=\mathrm{i} \sum_{k=1}^{3} \varepsilon_{i j k} K_{k} \psi(x), \quad \psi \in \mathcal{S}\left(\mathbb{R}^{3}\right), K_{j} \in\left\{L_{j}, p_{j}, x_{j}\right\}, \tag{8.19}
\end{equation*}
$$

and these algebraic commutation relations are often used to derive information on the point spectra of these operators. In this respect the domain

$$
\begin{equation*}
\mathfrak{D}=\operatorname{span}\left\{\left.x^{\alpha} \mathrm{e}^{-\frac{x^{2}}{2}} \right\rvert\, \alpha \in \mathbb{N}_{0}^{n}\right\} \subset \mathcal{S}\left(\mathbb{R}^{n}\right) \tag{8.20}
\end{equation*}
$$

is often used. It has the nice property that the finite dimensional subspaces

$$
\begin{equation*}
\mathfrak{D}_{k}=\operatorname{span}\left\{\left.x^{\alpha} \mathrm{e}^{-\frac{x^{2}}{2}}| | \alpha \right\rvert\, \leq k\right\} \tag{8.21}
\end{equation*}
$$

are invariant under $L_{j}$ (and hence they reduce $L_{j}$ ).
Lemma 8.3. The subspace $\mathfrak{D} \subset L^{2}\left(\mathbb{R}^{n}\right)$ defined in (8.20) is dense.
Proof. By Lemma 1.10 it suffices to consider the case $n=1$. Suppose $\langle\varphi, \psi\rangle=0$ for every $\psi \in \mathfrak{D}$. Then

$$
\frac{1}{\sqrt{2 \pi}} \int \overline{\varphi(x)} \mathrm{e}^{-\frac{x^{2}}{2}} \sum_{j=1}^{k} \frac{(\mathrm{i} t x)^{j}}{j!} d x=0
$$

for any finite $k$ and hence also in the limit $k \rightarrow \infty$ by the dominated convergence theorem. But the limit is the Fourier transform of $\overline{\varphi(x)} \mathrm{e}^{-\frac{x^{2}}{2}}$, which shows that this function is zero. Hence $\varphi(x)=0$.

Since $\mathfrak{D}$ is invariant under the unitary groups generated by $L_{j}$, the operators $L_{j}$ are essentially self-adjoint on $\mathfrak{D}$ by Corollary 5.3.

Introducing $L^{2}=L_{1}^{2}+L_{2}^{2}+L_{3}^{2}$, it is straightforward to check

$$
\begin{equation*}
\left[L^{2}, L_{j}\right] \psi(x)=0, \quad \psi \in \mathcal{S}\left(\mathbb{R}^{3}\right) \tag{8.22}
\end{equation*}
$$

Moreover, $\mathfrak{D}_{k}$ is invariant under $L^{2}$ and $L_{3}$ and hence $\mathfrak{D}_{k}$ reduces $L^{2}$ and $L_{3}$. In particular, $L^{2}$ and $L_{3}$ are given by finite matrices on $\mathfrak{D}_{k}$. Now
let $\mathfrak{H}_{m}=\operatorname{Ker}\left(L_{3}-m\right)$ and denote by $P_{k}$ the projector onto $\mathfrak{D}_{k}$. Since $L^{2}$ and $L_{3}$ commute on $\mathfrak{D}_{k}$, the space $P_{k} \mathfrak{H}_{m}$ is invariant under $L^{2}$, which shows that we can choose an orthonormal basis consisting of eigenfunctions of $L^{2}$ for $P_{k} \mathfrak{H}_{m}$. Increasing $k$, we get an orthonormal set of simultaneous eigenfunctions whose span is equal to $\mathfrak{D}$. Hence there is an orthonormal basis of simultaneous eigenfunctions of $L^{2}$ and $L_{3}$.

Now let us try to draw some further consequences by using the commutation relations (8.19). (All commutation relations below hold for $\psi \in \mathcal{S}\left(\mathbb{R}^{3}\right)$.) Denote by $\mathfrak{H}_{l, m}$ the set of all functions in $\mathfrak{D}$ satisfying

$$
\begin{equation*}
L_{3} \psi=m \psi, \quad L^{2} \psi=l(l+1) \psi . \tag{8.23}
\end{equation*}
$$

By $L^{2} \geq 0$ and $\sigma\left(L_{3}\right) \subseteq \mathbb{Z}$ we can restrict our attention to the case $l \geq 0$ and $m \in \mathbb{Z}$.

First introduce two new operators

$$
\begin{equation*}
L_{ \pm}=L_{1} \pm \mathrm{i} L_{2}, \quad\left[L_{3}, L_{ \pm}\right]= \pm L_{ \pm} . \tag{8.24}
\end{equation*}
$$

Then, for every $\psi \in \mathfrak{H}_{l, m}$ we have

$$
\begin{equation*}
L_{3}\left(L_{ \pm} \psi\right)=(m \pm 1)\left(L_{ \pm} \psi\right), \quad L^{2}\left(L_{ \pm} \psi\right)=l(l+1)\left(L_{ \pm} \psi\right) ; \tag{8.25}
\end{equation*}
$$

that is, $L_{ \pm} \mathfrak{H}_{l, m} \rightarrow \mathfrak{H}_{l, m \pm 1}$. Moreover, since

$$
\begin{equation*}
L^{2}=L_{3}^{2} \pm L_{3}+L_{\mp} L_{ \pm}, \tag{8.26}
\end{equation*}
$$

we obtain

$$
\begin{equation*}
\left\|L_{ \pm} \psi\right\|^{2}=\left\langle\psi, L_{\mp} L_{ \pm} \psi\right\rangle=(l(l+1)-m(m \pm 1))\|\psi\| \tag{8.27}
\end{equation*}
$$

for every $\psi \in \mathfrak{H}_{l, m}$. If $\psi \neq 0$, we must have $l(l+1)-m(m \pm 1) \geq 0$, which shows $\mathfrak{H}_{l, m}=\{0\}$ for $|m|>l$. Moreover, $L_{ \pm} \mathfrak{H}_{l, m} \rightarrow \mathfrak{H}_{l, m \pm 1}$ is injective unless $|m|=l$. Hence we must have $\mathfrak{H}_{l, m}=\{0\}$ for $l \notin \mathbb{N}_{0}$.

Up to this point we know $\sigma\left(L^{2}\right) \subseteq\left\{l(l+1) \mid l \in \mathbb{N}_{0}\right\}, \sigma\left(L_{3}\right) \subseteq \mathbb{Z}$. In order to show that equality holds in both cases, we need to show that $\mathfrak{H}_{l, m} \neq\{0\}$ for $l \in \mathbb{N}_{0}, m=-l,-l+1, \ldots, l-1, l$. First of all we observe

$$
\begin{equation*}
\psi_{0,0}(x)=\frac{1}{\pi^{3 / 4}} \mathrm{e}^{-\frac{x^{2}}{2}} \in \mathfrak{H}_{0,0} . \tag{8.28}
\end{equation*}
$$

Next, we note that (8.19) implies

$$
\begin{align*}
& {\left[L_{3}, x_{ \pm}\right]= \pm x_{ \pm}, \quad x_{ \pm}=x_{1} \pm \mathrm{i} x_{2},} \\
& {\left[L_{ \pm}, x_{ \pm}\right]=0, \quad\left[L_{ \pm}, x_{\mp}\right]= \pm 2 x_{3},} \\
& {\left[L^{2}, x_{ \pm}\right]=2 x_{ \pm}\left(1 \pm L_{3}\right) \mp 2 x_{3} L_{ \pm} .} \tag{8.29}
\end{align*}
$$

Hence if $\psi \in \mathfrak{H}_{l, l}$, then $\left(x_{1} \pm \mathrm{i} x_{2}\right) \psi \in \mathfrak{H}_{l \pm 1, l \pm 1}$. Thus

$$
\begin{equation*}
\psi_{l, l}(x)=\frac{1}{\sqrt{l!}}\left(x_{1} \pm \mathrm{i} x_{2}\right)^{l} \psi_{0,0}(x) \in \mathfrak{H}_{l, l}, \tag{8.30}
\end{equation*}
$$

respectively,

$$
\begin{equation*}
\psi_{l, m}(x)=\sqrt{\frac{(l+m)!}{(l-m)!(2 l)!}} L_{-}^{l-m} \psi_{l, l}(x) \in \mathfrak{H}_{l, m} . \tag{8.31}
\end{equation*}
$$

The constants are chosen such that $\left\|\psi_{l, m}\right\|=1$.
In summary,
Theorem 8.4. There exists an orthonormal basis of simultaneous eigenvectors for the operators $L^{2}$ and $L_{j}$. Moreover, their spectra are given by

$$
\begin{equation*}
\sigma\left(L^{2}\right)=\left\{l(l+1) \mid l \in \mathbb{N}_{0}\right\}, \quad \sigma\left(L_{3}\right)=\mathbb{Z} \tag{8.32}
\end{equation*}
$$

We will give an alternate derivation of this result in Section 10.3.

### 8.3. The harmonic oscillator

Finally, let us consider another important model whose algebraic structure is similar to those of the angular momentum, the harmonic oscillator

$$
\begin{equation*}
H=H_{0}+\omega^{2} x^{2}, \quad \omega>0 \tag{8.33}
\end{equation*}
$$

We will choose as domain

$$
\begin{equation*}
\mathfrak{D}(H)=\mathfrak{D}=\operatorname{span}\left\{\left.x^{\alpha} \mathrm{e}^{-\frac{x^{2}}{2}} \right\rvert\, \alpha \in \mathbb{N}_{0}^{3}\right\} \subseteq L^{2}\left(\mathbb{R}^{3}\right) \tag{8.34}
\end{equation*}
$$

from our previous section.
We will first consider the one-dimensional case. Introducing

$$
\begin{equation*}
A_{ \pm}=\frac{1}{\sqrt{2}}\left(\sqrt{\omega} x \mp \frac{1}{\sqrt{\omega}} \frac{d}{d x}\right), \quad \mathfrak{D}\left(A_{ \pm}\right)=\mathfrak{D} \tag{8.35}
\end{equation*}
$$

we have

$$
\begin{equation*}
\left[A_{-}, A_{+}\right]=1 \tag{8.36}
\end{equation*}
$$

and

$$
\begin{equation*}
H=\omega(2 N+1), \quad N=A_{+} A_{-}, \quad \mathfrak{D}(N)=\mathfrak{D}, \tag{8.37}
\end{equation*}
$$

for any function in $\mathfrak{D}$. In particular, note that $\mathfrak{D}$ is invariant under $A_{ \pm}$.
Moreover, since

$$
\begin{equation*}
\left[N, A_{ \pm}\right]= \pm A_{ \pm}, \tag{8.38}
\end{equation*}
$$

we see that $N \psi=n \psi$ implies $N A_{ \pm} \psi=(n \pm 1) A_{ \pm} \psi$. Moreover, $\left\|A_{+} \psi\right\|^{2}=$ $\left\langle\psi, A_{-} A_{+} \psi\right\rangle=(n+1)\|\psi\|^{2}$, respectively, $\left\|A_{-} \psi\right\|^{2}=n\|\psi\|^{2}$, in this case and hence we conclude that $\sigma_{p}(N) \subseteq \mathbb{N}_{0}$.

If $N \psi_{0}=0$, then we must have $A_{-} \psi=0$ and the normalized solution of this last equation is given by

$$
\begin{equation*}
\psi_{0}(x)=\left(\frac{\omega}{\pi}\right)^{1 / 4} \mathrm{e}^{-\frac{\omega x^{2}}{2}} \in \mathfrak{D} \tag{8.39}
\end{equation*}
$$

Hence

$$
\begin{equation*}
\psi_{n}(x)=\frac{1}{\sqrt{n!}} A_{+}^{n} \psi_{0}(x) \tag{8.40}
\end{equation*}
$$

is a normalized eigenfunction of $N$ corresponding to the eigenvalue $n$. Moreover, since

$$
\begin{equation*}
\psi_{n}(x)=\frac{1}{\sqrt{2^{n} n!}}\left(\frac{\omega}{\pi}\right)^{1 / 4} H_{n}(\sqrt{\omega} x) \mathrm{e}^{-\frac{\omega x^{2}}{2}} \tag{8.41}
\end{equation*}
$$

where $H_{n}(x)$ is a polynomial of degree $n$ given by

$$
\begin{equation*}
H_{n}(x)=\mathrm{e}^{\frac{x^{2}}{2}}\left(x-\frac{d}{d x}\right)^{n} \mathrm{e}^{-\frac{x^{2}}{2}}=(-1)^{n} \mathrm{e}^{x^{2}} \frac{d^{n}}{d x^{n}} \mathrm{e}^{-x^{2}} \tag{8.42}
\end{equation*}
$$

we conclude $\operatorname{span}\left\{\psi_{n}\right\}=\mathfrak{D}$. The polynomials $H_{n}(x)$ are called Hermite polynomials.

In summary,
Theorem 8.5. The harmonic oscillator $H$ is essentially self-adjoint on $\mathfrak{D}$ and has an orthonormal basis of eigenfunctions

$$
\begin{equation*}
\psi_{n_{1}, n_{2}, n_{3}}(x)=\psi_{n_{1}}\left(x_{1}\right) \psi_{n_{2}}\left(x_{2}\right) \psi_{n_{3}}\left(x_{3}\right), \tag{8.43}
\end{equation*}
$$

with $\psi_{n_{j}}\left(x_{j}\right)$ from (8.41). The spectrum is given by

$$
\begin{equation*}
\sigma(H)=\left\{(2 n+3) \omega \mid n \in \mathbb{N}_{0}\right\} . \tag{8.44}
\end{equation*}
$$

Finally, there is also a close connection with the Fourier transformation. Without restriction we choose $\omega=1$ and consider only one-dimension. Then it easy to verify that $H$ commutes with the Fourier transformation,

$$
\begin{equation*}
\mathcal{F} H=H \mathcal{F} \tag{8.45}
\end{equation*}
$$

on $\mathfrak{D}$. Moreover, by $\mathcal{F} A_{ \pm}=\mp \mathrm{i} A_{ \pm} \mathcal{F}$ we even infer

$$
\begin{equation*}
\mathcal{F} \psi_{n}=\frac{1}{\sqrt{n!}} \mathcal{F} A_{+}^{n} \psi_{0}=\frac{(-\mathrm{i})^{n}}{\sqrt{n!}} A_{+}^{n} \mathcal{F} \psi_{0}=(-\mathrm{i})^{n} \psi_{n} \tag{8.46}
\end{equation*}
$$

since $\mathcal{F} \psi_{0}=\psi_{0}$ by Lemma 7.3. In particular,

$$
\begin{equation*}
\sigma(\mathcal{F})=\left\{z \in \mathbb{C} \mid z^{4}=1\right\} \tag{8.47}
\end{equation*}
$$

### 8.4. Abstract commutation

The considerations of the previous section can be generalized as follows. First of all, the starting point was a factorization of $H$ according to $H=A^{*} A$ (note that $A_{ \pm}$from the previous section are adjoint to each other when restricted to $\mathfrak{D}$ ). Then it turned out that commuting both operators just corresponds to a shift of $H$; that is, $A A^{*}=H+c$. Hence one could exploit the close spectral relation of $A^{*} A$ and $A A^{*}$ to compute both the eigenvalues and eigenvectors.

More generally, let $A$ be a closed operator and recall that $H_{0}=A^{*} A$ is a self-adjoint operator (cf. Problem 2.12) with $\operatorname{Ker}\left(H_{0}\right)=\operatorname{Ker}(A)$. Similarly, $H_{1}=A A^{*}$ is a self-adjoint operator with $\operatorname{Ker}\left(H_{1}\right)=\operatorname{Ker}\left(A^{*}\right)$.
Theorem 8.6. Let $A$ be a closed operator. The operators $H_{0}=\left.A^{*} A\right|_{\operatorname{Ker}(A)^{\perp}}$ and $H_{1}=\left.A A^{*}\right|_{\operatorname{Ker}\left(A^{*}\right)^{\perp}}$ are unitarily equivalent.

If $H_{0} \psi_{0}=E \psi_{0}, \psi_{0} \in \mathfrak{D}\left(H_{0}\right)$, then $\psi_{1}=A \psi_{0} \in \mathfrak{D}\left(H_{1}\right)$ with $H_{1} \psi_{1}=\psi_{1}$ and $\left\|\psi_{1}\right\|=\sqrt{E}\left\|\psi_{0}\right\|$. Moreover,

$$
\begin{equation*}
R_{H_{1}}(z) \supseteq \frac{1}{z}\left(A R_{H_{0}}(z) A^{*}-1\right), \quad R_{H_{0}}(z) \supseteq \frac{1}{z}\left(A^{*} R_{H_{1}}(z) A-1\right) . \tag{8.48}
\end{equation*}
$$

Proof. Introducing $|A|=H_{0}^{1 / 2}$, we have the polar decomposition (Problem 3.11)

$$
A=U|A|,
$$

where

$$
U: \operatorname{Ker}(A)^{\perp} \rightarrow \operatorname{Ker}\left(A^{*}\right)^{\perp}
$$

is unitary. Taking adjoints, we have (Problem 2.3)

$$
A^{*}=|A| U^{*}
$$

and thus $H_{1}=A A^{*}=U|A||A| U^{*}=U H_{0} U^{*}$ shows the claimed unitary equivalence.

The claims about the eigenvalues are straightforward (for the norm note $\left.A \psi_{0}=\sqrt{E} U \psi_{0}\right)$. To see the connection between the resolvents, abbreviate $P_{1}=P_{H_{1}}(\{0\})$. Then

$$
\begin{aligned}
R_{H_{1}}(z) & =R_{H_{1}}(z)\left(1-P_{1}\right)+\frac{1}{z} P_{1}=U R_{H_{0}} U^{*}+\frac{1}{z} P_{1} \\
& \supseteq \frac{1}{z}\left(U\left(\left|H_{0}\right|^{1 / 2} R_{H_{0}}\left|H_{0}\right|^{1 / 2}-1\right) U^{*}+P_{1}\right) \\
& =\frac{1}{z}\left(A R_{H_{0}} A^{*}+\left(1-P_{1}\right)+P_{1}\right)=\frac{1}{z}\left(A R_{H_{0}} A^{*}+1\right),
\end{aligned}
$$

where we have used $U U^{*}=1-P_{1}$.
We will use this result to compute the eigenvalues and eigenfunctions of the hydrogen atom in Section 10.4. In the physics literature this approach is also known as supersymmetric quantum mechanics.
Problem 8.2. Show that $H_{0}=-\frac{d^{2}}{d x^{2}}+q$ can formally (i.e., ignoring domains) be written as $H_{0}=A A^{*}$, where $A=-\frac{d}{d x}+\phi$, if the differential equation $\psi^{\prime \prime}+q \psi=0$ has a positive solution. Compute $H_{1}=A^{*} A$. (Hint: $\left.\phi=\frac{\psi^{\prime}}{\psi}.\right)$
Problem 8.3. Take $H_{0}=-\frac{d^{2}}{d x^{2}}+\lambda, \lambda>0$, and compute $H_{1}$. What about domains?

## One-dimensional Schrödinger operators

### 9.1. Sturm-Liouville operators

In this section we want to illustrate some of the results obtained thus far by investigating a specific example, the Sturm-Liouville equation

$$
\begin{equation*}
\tau f(x)=\frac{1}{r(x)}\left(-\frac{d}{d x} p(x) \frac{d}{d x} f(x)+q(x) f(x)\right), \quad f, p f^{\prime} \in A C_{l o c}(I) \tag{9.1}
\end{equation*}
$$

The case $p=r=1$ can be viewed as the model of a particle in onedimension in the external potential $q$. Moreover, the case of a particle in three dimensions can in some situations be reduced to the investigation of Sturm-Liouville equations. In particular, we will see how this works when explicitly solving the hydrogen atom.

The suitable Hilbert space is

$$
\begin{equation*}
L^{2}((a, b), r(x) d x), \quad\langle f, g\rangle=\int_{a}^{b} f(x)^{*} g(x) r(x) d x \tag{9.2}
\end{equation*}
$$

where $I=(a, b) \subseteq \mathbb{R}$ is an arbitrary open interval.
We require
(i) $p^{-1} \in L_{l o c}^{1}(I)$, positive,
(ii) $q \in L_{l o c}^{1}(I)$, real-valued,
(iii) $r \in L_{l o c}^{1}(I)$, positive.

If $a$ is finite and if $p^{-1}, q, r \in L^{1}((a, c))(c \in I)$, then the Sturm-Liouville equation (9.1) is called regular at $a$. Similarly for $b$. If it is regular at both $a$ and $b$, it is called regular.

The maximal domain of definition for $\tau$ in $L^{2}(I, r d x)$ is given by

$$
\begin{equation*}
\mathfrak{D}(\tau)=\left\{f \in L^{2}(I, r d x) \mid f, p f^{\prime} \in A C_{l o c}(I), \tau f \in L^{2}(I, r d x)\right\} \tag{9.3}
\end{equation*}
$$

It is not clear that $\mathfrak{D}(\tau)$ is dense unless (e.g.) $p \in A C_{l o c}(I), p^{\prime}, q \in L_{l o c}^{2}(I)$, $r^{-1} \in L_{l o c}^{\infty}(I)$ since $C_{0}^{\infty}(I) \subset \mathfrak{D}(\tau)$ in this case. We will defer the general case to Lemma 9.4 below.

Since we are interested in self-adjoint operators $H$ associated with (9.1), we perform a little calculation. Using integration by parts (twice), we obtain the Lagrange identity $(a<c<d<b)$

$$
\begin{equation*}
\int_{c}^{d} g^{*}(\tau f) r d y=W_{d}\left(g^{*}, f\right)-W_{c}\left(g^{*}, f\right)+\int_{c}^{d}(\tau g)^{*} f r d y \tag{9.4}
\end{equation*}
$$

for $f, g, p f^{\prime}, p g^{\prime} \in A C_{l o c}(I)$, where

$$
\begin{equation*}
W_{x}\left(f_{1}, f_{2}\right)=\left(p\left(f_{1} f_{2}^{\prime}-f_{1}^{\prime} f_{2}\right)\right)(x) \tag{9.5}
\end{equation*}
$$

is called the modified Wronskian.
Equation (9.4) also shows that the Wronskian of two solutions of $\tau u=z u$ is constant

$$
\begin{equation*}
W_{x}\left(u_{1}, u_{2}\right)=W\left(u_{1}, u_{2}\right), \quad \tau u_{1,2}=z u_{1,2} \tag{9.6}
\end{equation*}
$$

Moreover, it is nonzero if and only if $u_{1}$ and $u_{2}$ are linearly independent (compare Theorem 9.1 below).

If we choose $f, g \in \mathfrak{D}(\tau)$ in (9.4), then we can take the limits $c \rightarrow a$ and $d \rightarrow b$, which results in

$$
\begin{equation*}
\langle g, \tau f\rangle=W_{b}\left(g^{*}, f\right)-W_{a}\left(g^{*}, f\right)+\langle\tau g, f\rangle, \quad f, g \in \mathfrak{D}(\tau) \tag{9.7}
\end{equation*}
$$

Here $W_{a, b}\left(g^{*}, f\right)$ has to be understood as a limit.
Finally, we recall the following well-known result from ordinary differential equations.

Theorem 9.1. Suppose $r g \in L_{l o c}^{1}(I)$. Then there exists a unique solution $f, p f^{\prime} \in A C_{l o c}(I)$ of the differential equation

$$
\begin{equation*}
(\tau-z) f=g, \quad z \in \mathbb{C} \tag{9.8}
\end{equation*}
$$

satisfying the initial condition

$$
\begin{equation*}
f(c)=\alpha, \quad\left(p f^{\prime}\right)(c)=\beta, \quad \alpha, \beta \in \mathbb{C}, \quad c \in I \tag{9.9}
\end{equation*}
$$

In addition, $f$ is entire with respect to $z$.

Proof. Introducing

$$
u=\binom{f}{p f^{\prime}}, \quad v=\binom{0}{r g},
$$

we can rewrite (9.8) as the linear first order system

$$
u^{\prime}-A u=v, \quad A(x)=\left(\begin{array}{cc}
0 & p^{-1}(x) \\
q(x)-z r(x) & 0
\end{array}\right) .
$$

Integrating with respect to $x$, we see that this system is equivalent to the Volterra integral equation

$$
u-K u=w, \quad(K u)(x)=\int_{c}^{x} A(y) u(y) d y, \quad w(x)=\binom{\alpha}{\beta}+\int_{c}^{x} v(y) d y .
$$

We will choose some $d \in(c, b)$ and consider the integral operator $K$ in the Banach space $C([c, d])$. Then for any $h \in C([c, d])$ and $x \in[c, d]$ we have the estimate

$$
\left|K^{n}(h)(x)\right| \leq \frac{a_{1}(x)^{n}}{n!}\|h\|, \quad a_{1}(x)=\int_{c}^{x} a(y) d y, a(x)=\|A(x)\|,
$$

which follows from induction

$$
\begin{aligned}
\left|K^{n+1}(h)(x)\right| & =\left|\int_{c}^{x} A(y) K^{n}(h)(y) d y\right| \leq \int_{c}^{x} a(y)\left|K^{n}(h)(y)\right| d y \\
& \leq\|h\| \int_{c}^{x} a(y) \frac{a_{1}(y)^{n}}{n!} d y=\frac{a_{1}(x)^{n+1}}{(n+1)!}\|h\| .
\end{aligned}
$$

Hence the unique solution of our integral equation is given by the Neumann series (show this)

$$
u(x)=\sum_{n=0}^{\infty} K^{n}(w)(x) .
$$

To see that the solution $u(x)$ is entire with respect to $z$, note that the partial sums are entire (in fact polynomial) in $z$ and hence so is the limit by uniform convergence with respect to $z$ in compact sets. An analogous argument for $d \in(a, c)$ finishes the proof.

Note that $f, p f^{\prime}$ can be extended continuously to a regular endpoint.
Lemma 9.2. Suppose $u_{1}, u_{2}$ are two solutions of $(\tau-z) u=0$ which satisfy $W\left(u_{1}, u_{2}\right)=1$. Then any other solution of (9.8) can be written as $(\alpha, \beta \in \mathbb{C})$

$$
\begin{align*}
& f(x)=u_{1}(x)\left(\alpha+\int_{c}^{x} u_{2} g r d y\right)+u_{2}(x)\left(\beta-\int_{c}^{x} u_{1} g r d y\right), \\
& f^{\prime}(x)=u_{1}^{\prime}(x)\left(\alpha+\int_{c}^{x} u_{2} g r d y\right)+u_{2}^{\prime}(x)\left(\beta-\int_{c}^{x} u_{1} g r d y\right) . \tag{9.10}
\end{align*}
$$

Note that the constants $\alpha, \beta$ coincide with those from Theorem 9.1 if $u_{1}(c)=$ $\left(p u_{2}^{\prime}\right)(c)=1$ and $\left(p u_{1}^{\prime}\right)(c)=u_{2}(c)=0$.

Proof. It suffices to check $\tau f-z f=g$. Differentiating the first equation of (9.10) gives the second. Next we compute

$$
\begin{aligned}
\left(p f^{\prime}\right)^{\prime} & =\left(p u_{1}^{\prime}\right)^{\prime}\left(\alpha+\int u_{2} g r d y\right)+\left(p u_{2}^{\prime}\right)^{\prime}\left(\beta-\int u_{1} g r d y\right)-W\left(u_{1}, u_{2}\right) g r \\
& =(q-z r) u_{1}\left(\alpha+\int u_{2} g r d y\right)+(q-z r) u_{2}\left(\beta-\int u_{1} g d y\right)-g r \\
& =(q-z r) f-g r
\end{aligned}
$$

which proves the claim.
Now we want to obtain a symmetric operator and hence we choose

$$
\begin{equation*}
A_{0} f=\tau f, \quad \mathfrak{D}\left(A_{0}\right)=\mathfrak{D}(\tau) \cap A C_{c}(I), \tag{9.11}
\end{equation*}
$$

where $A C_{c}(I)$ denotes the functions in $A C(I)$ with compact support. This definition clearly ensures that the Wronskian of two such functions vanishes on the boundary, implying that $A_{0}$ is symmetric by virtue of (9.7). Our first task is to compute the closure of $A_{0}$ and its adjoint. For this the following elementary fact will be needed.
Lemma 9.3. Suppose $V$ is a vector space and $l, l_{1}, \ldots, l_{n}$ are linear functionals (defined on all of $V$ ) such that $\bigcap_{j=1}^{n} \operatorname{Ker}\left(l_{j}\right) \subseteq \operatorname{Ker}(l)$. Then $l=$ $\sum_{j=0}^{n} \alpha_{j} l_{j}$ for some constants $\alpha_{j} \in \mathbb{C}$.

Proof. First of all it is no restriction to assume that the functionals $l_{j}$ are linearly independent. Then the map $L: V \rightarrow \mathbb{C}^{n}, f \mapsto\left(l_{1}(f), \ldots, l_{n}(f)\right)$ is surjective (since $x \in \operatorname{Ran}(L)^{\perp}$ implies $\sum_{j=1}^{n} x_{j} l_{j}(f)=0$ for all $f$ ). Hence there are vectors $f_{k} \in V$ such that $l_{j}\left(f_{k}\right)=0$ for $j \neq k$ and $l_{j}\left(f_{j}\right)=1$. Then $f-\sum_{j=1}^{n} l_{j}(f) f_{j} \in \bigcap_{j=1}^{n} \operatorname{Ker}\left(l_{j}\right)$ and hence $l(f)-\sum_{j=1}^{n} l_{j}(f) l\left(f_{j}\right)=0$. Thus we can choose $\alpha_{j}=l\left(f_{j}\right)$.

Now we are ready to prove
Lemma 9.4. The operator $A_{0}$ is densely defined and its closure is given by

$$
\begin{equation*}
\overline{A_{0}} f=\tau f, \quad \mathfrak{D}\left(\overline{A_{0}}\right)=\left\{f \in \mathfrak{D}(\tau) \mid W_{a}(f, g)=W_{b}(f, g)=0, \forall g \in \mathfrak{D}(\tau)\right\} . \tag{9.12}
\end{equation*}
$$

Its adjoint is given by

$$
\begin{equation*}
A_{0}^{*} f=\tau f, \quad \mathfrak{D}\left(A_{0}^{*}\right)=\mathfrak{D}(\tau) . \tag{9.13}
\end{equation*}
$$

Proof. We start by computing $A_{0}^{*}$ and ignore the fact that we do not know whether $\mathfrak{D}\left(A_{0}\right)$ is dense for now.

By (9.7) we have $\mathfrak{D}(\tau) \subseteq \mathfrak{D}\left(A_{0}^{*}\right)$ and it remains to show $\mathfrak{D}\left(A_{0}^{*}\right) \subseteq \mathfrak{D}(\tau)$. If $h \in \mathfrak{D}\left(A_{0}^{*}\right)$, we must have

$$
\left\langle h, A_{0} f\right\rangle=\langle k, f\rangle, \quad \forall f \in \mathfrak{D}\left(A_{0}\right),
$$

for some $k \in L^{2}(I, r d x)$. Using (9.10), we can find a $\tilde{h}$ such that $\tau \tilde{h}=k$ and from integration by parts we obtain

$$
\begin{equation*}
\int_{a}^{b}(h(x)-\tilde{h}(x))^{*}(\tau f)(x) r(x) d x=0, \quad \forall f \in \mathfrak{D}\left(A_{0}\right) . \tag{9.14}
\end{equation*}
$$

Clearly we expect that $h-\tilde{h}$ will be a solution of $\tau u=0$ and to prove this, we will invoke Lemma 9.3. Therefore we consider the linear functionals

$$
l(g)=\int_{a}^{b}(h(x)-\tilde{h}(x))^{*} g(x) r(x) d x, \quad l_{j}(g)=\int_{a}^{b} u_{j}(x)^{*} g(x) r(x) d x,
$$

on $L_{c}^{2}(I, r d x)$, where $u_{j}$ are two solutions of $\tau u=0$ with $W\left(u_{1}, u_{2}\right) \neq 0$. Then we have $\operatorname{Ker}\left(l_{1}\right) \cap \operatorname{Ker}\left(l_{2}\right) \subseteq \operatorname{Ker}(l)$. In fact, if $g \in \operatorname{Ker}\left(l_{1}\right) \cap \operatorname{Ker}\left(l_{2}\right)$, then

$$
f(x)=u_{1}(x) \int_{a}^{x} u_{2}(y) g(y) r(y) d y+u_{2}(x) \int_{x}^{b} u_{1}(y) g(y) r(y) d y
$$

is in $\mathfrak{D}\left(A_{0}\right)$ and $g=\tau f \in \operatorname{Ker}(l)$ by (9.14). Now Lemma 9.3 implies

$$
\int_{a}^{b}\left(h(x)-\tilde{h}(x)+\alpha_{1} u_{1}(x)+\alpha_{2} u_{2}(x)\right)^{*} g(x) r(x) d x=0, \quad \forall g \in L_{c}^{2}(I, r d x)
$$

and hence $h=\tilde{h}+\alpha_{1} u_{1}+\alpha_{2} u_{2} \in \mathfrak{D}(\tau)$.
Now what if $\mathfrak{D}\left(A_{0}\right)$ were not dense? Then there would be some freedom in the choice of $k$ since we could always add a component in $\mathfrak{D}\left(A_{0}\right)^{\perp}$. So suppose we have two choices $k_{1} \neq k_{2}$. Then by the above calculation, there are corresponding functions $\tilde{h}_{1}$ and $\tilde{h}_{2}$ such that $h=\tilde{h}_{1}+\alpha_{1,1} u_{1}+\alpha_{1,2} u_{2}=$ $\tilde{h}_{2}+\alpha_{2,1} u_{1}+\alpha_{2,2} u_{2}$. In particular, $\tilde{h}_{1}-\tilde{h}_{2}$ is in the kernel of $\tau$ and hence $k_{1}=\tau \tilde{h}_{1}=\tau \tilde{h}_{2}=k_{2}$, a contradiction to our assumption.

Next we turn to $\overline{A_{0}}$. Denote the set on the right-hand side of (9.12) by $\mathfrak{D}$. Then we have $\mathfrak{D} \subseteq \mathfrak{D}\left(A_{0}^{* *}\right)=\bar{A}_{0}$ by (9.7). Conversely, since $\overline{A_{0}} \subseteq A_{0}^{*}$, we can use (9.7) to conclude

$$
W_{a}(f, h)+W_{b}(f, h)=0, \quad f \in \mathfrak{D}\left(\overline{A_{0}}\right), h \in \mathfrak{D}\left(A_{0}^{*}\right) .
$$

Now replace $h$ by a $\tilde{h} \in \mathfrak{D}\left(A_{0}^{*}\right)$ which coincides with $h$ near $a$ and vanishes identically near $b$ (Problem 9.1). Then $W_{a}(f, h)=W_{a}(f, \tilde{h})+W_{b}(f, \tilde{h})=0$. Finally, $W_{b}(f, h)=-W_{a}(f, h)=0$ shows $f \in \mathfrak{D}$.

Example. If $\tau$ is regular at $a$, then $W_{a}(f, g)=0$ for all $g \in \mathfrak{D}(\tau)$ if and only if $f(a)=\left(p f^{\prime}\right)(a)=0$. This follows since we can prescribe the values of $g(a),\left(p g^{\prime}\right)(a)$ for $g \in \mathfrak{D}(\tau)$ arbitrarily.

This result shows that any self-adjoint extension of $A_{0}$ must lie between $\bar{A}_{0}$ and $A_{0}^{*}$. Moreover, self-adjointness seems to be related to the Wronskian of two functions at the boundary. Hence we collect a few properties first.

Lemma 9.5. Suppose $v \in \mathfrak{D}(\tau)$ with $W_{a}\left(v^{*}, v\right)=0$ and suppose there is a $\hat{f} \in \mathfrak{D}(\tau)$ with $W_{a}\left(v^{*}, \hat{f}\right) \neq 0$. Then, for $f, g \in \mathfrak{D}(\tau)$, we have

$$
\begin{equation*}
W_{a}(v, f)=0 \quad \Leftrightarrow \quad W_{a}\left(v, f^{*}\right)=0 \tag{9.15}
\end{equation*}
$$

and

$$
\begin{equation*}
W_{a}(v, f)=W_{a}(v, g)=0 \quad \Rightarrow \quad W_{a}\left(g^{*}, f\right)=0 . \tag{9.16}
\end{equation*}
$$

Proof. For all $f_{1}, \ldots, f_{4} \in \mathfrak{D}(\tau)$ we have the Plücker identity

$$
\begin{equation*}
W_{x}\left(f_{1}, f_{2}\right) W_{x}\left(f_{3}, f_{4}\right)+W_{x}\left(f_{1}, f_{3}\right) W_{x}\left(f_{4}, f_{2}\right)+W_{x}\left(f_{1}, f_{4}\right) W_{x}\left(f_{2}, f_{3}\right)=0 \tag{9.17}
\end{equation*}
$$

which remains valid in the limit $x \rightarrow a$. Choosing $f_{1}=v, f_{2}=f, f_{3}=$ $v^{*}, f_{4}=\hat{f}$, we infer (9.15). Choosing $f_{1}=f, f_{2}=g^{*}, f_{3}=v, f_{4}=\hat{f}$, we infer (9.16).

Problem 9.1. Given $\alpha, \beta, \gamma, \delta$, show that there is a function $f$ in $\mathfrak{D}(\tau)$ restricted to $[c, d] \subseteq(a, b)$ such that $f(c)=\alpha,\left(p f^{\prime}\right)(c)=\beta$ and $f(d)=\gamma$, $\left(p f^{\prime}\right)(c)=\delta$. (Hint: Lemma 9.2.)
Problem 9.2. Let $A_{0}=-\frac{d^{2}}{d x^{2}}, \mathfrak{D}\left(A_{0}\right)=\left\{f \in H^{2}[0,1] \mid f(0)=f(1)=0\right\}$ and $B=q, \mathfrak{D}(B)=\left\{f \in L^{2}(0,1) \mid q f \in L^{2}(0,1)\right\}$. Find a $q \in L^{1}(0,1)$ such that $\mathfrak{D}\left(A_{0}\right) \cap \mathfrak{D}(B)=\{0\}$. (Hint: Problem 0.30.)

Problem 9.3. Let $\phi \in L_{l o c}^{1}(I)$. Define

$$
A_{ \pm}= \pm \frac{d}{d x}+\phi, \quad \mathfrak{D}\left(A_{ \pm}\right)=\left\{f \in L^{2}(I) \mid f \in A C(I), \pm f^{\prime}+\phi f \in L^{2}(I)\right\}
$$

and $A_{0, \pm}=\left.A_{ \pm}\right|_{A C_{c}(I)}$. Show $A_{0, \pm}^{*}=A_{\mp}$ and

$$
\mathfrak{D}\left(\overline{A_{0, \pm}}\right)=\left\{f \in \mathfrak{D}\left(A_{ \pm}\right) \mid \lim _{x \rightarrow a, b} f(x) g(x)=0, \forall g \in \mathfrak{D}\left(A_{\mp}\right)\right\} .
$$

In particular, show that the limits above exist.
Problem 9.4 (Liouville normal form). Show that every Sturm-Liouville equation can be transformed into one with $r=p=1$ as follows: Show that the transformation $U: L^{2}((a, b), r d x) \rightarrow L^{2}(0, c), c=\int_{a}^{b} \frac{r(t)}{p(t)} d t$, defined via $u(x) \mapsto v(y)$, where

$$
y(x)=\int_{a}^{x} \sqrt{\frac{r(t)}{p(t)}} d t, \quad v(y)=\sqrt[4]{r(x(y)) p(x(y))} u(x(y))
$$

is unitary. Moreover, if $p, r, p^{\prime}, r^{\prime} \in A C(a, b)$, then

$$
-\left(p u^{\prime}\right)^{\prime}+q u=r \lambda u
$$

transforms into

$$
-v^{\prime \prime}+Q v=\lambda v,
$$

where

$$
Q=q-\frac{(p r)^{1 / 4}}{r}\left(p\left((p r)^{-1 / 4}\right)^{\prime}\right)^{\prime} .
$$

### 9.2. Weyl's limit circle, limit point alternative

Inspired by Lemma 9.5, we make the following definition: We call $\tau$ limit circle (l.c.) at $a$ if there is a $v \in \mathfrak{D}(\tau)$ with $W_{a}\left(v^{*}, v\right)=0$ such that $W_{a}(v, f) \neq 0$ for at least one $f \in \mathfrak{D}(\tau)$. Otherwise $\tau$ is called limit point (l.p.) at $a$ and similarly for $b$.

Example. If $\tau$ is regular at $a$, it is limit circle at $a$. Since

$$
\begin{equation*}
W_{a}(v, f)=\left(p f^{\prime}\right)(a) v(a)-\left(p v^{\prime}\right)(a) f(a), \tag{9.18}
\end{equation*}
$$

any real-valued $v$ with $\left(v(a),\left(p v^{\prime}\right)(a)\right) \neq(0,0)$ works.
Note that if $W_{a}(f, v) \neq 0$, then $W_{a}(f, \operatorname{Re}(v)) \neq 0$ or $W_{a}(f, \operatorname{Im}(v)) \neq 0$. Hence it is no restriction to assume that $v$ is real and $W_{a}\left(v^{*}, v\right)=0$ is trivially satisfied in this case. In particular, $\tau$ is limit point if and only if $W_{a}(f, g)=0$ for all $f, g \in \mathfrak{D}(\tau)$.

Theorem 9.6. If $\tau$ is l.c. at $a$, then let $v \in \mathfrak{D}(\tau)$ with $W_{a}\left(v^{*}, v\right)=0$ and $W_{a}(v, f) \neq 0$ for some $f \in \mathfrak{D}(\tau)$. Similarly, if $\tau$ is l.c. at $b$, let $w$ be an analogous function. Then the operator

$$
\begin{align*}
A: \mathfrak{D}(A) & \rightarrow L^{2}(I, r d x)  \tag{9.19}\\
f & \mapsto \tau f
\end{align*}
$$

with

$$
\begin{array}{ll}
\mathfrak{D}(A)=\{f \in \mathfrak{D}(\tau) \mid & W_{a}(v, f)=0 \text { if l.c. at } a \\
& \left.W_{b}(w, f)=0 \text { if l.c. at } b\right\} \tag{9.20}
\end{array}
$$

is self-adjoint. Moreover, the set

$$
\begin{align*}
\mathfrak{D}_{1}=\{f \in \mathfrak{D}(\tau) \mid & \exists x_{0} \in I: \forall x \in\left(a, x_{0}\right), W_{x}(v, f)=0,  \tag{9.21}\\
& \left.\exists x_{1} \in I: \forall x \in\left(x_{1}, b\right), W_{x}(w, f)=0\right\}
\end{align*}
$$

is a core for $A$.
Proof. By Lemma 9.5, $A$ is symmetric and hence $A \subseteq A^{*} \subseteq A_{0}^{*}$. Let $g \in$ $\mathfrak{D}\left(A^{*}\right)$. As in the computation of $\overline{A_{0}}$ we conclude $W_{a}(f, g)=W_{b}(f, g)=0$ for all $f \in \mathfrak{D}(A)$. Moreover, we can choose $f$ such that it coincides with $v$ near $a$ and hence $W_{a}(v, g)=0$. Similarly $W_{b}(w, g)=0$; that is, $g \in \mathfrak{D}(A)$.

To see that $\mathfrak{D}_{1}$ is a core, let $A_{1}$ be the corresponding operator and observe that the argument from above, with $A_{1}$ in place of $A$, shows $A_{1}^{*}=A$.

The name limit circle, respectively, limit point, stems from the original approach of Weyl, who considered the set of solutions $\tau u=z u, z \in \mathbb{C} \backslash \mathbb{R}$, which satisfy $W_{x}\left(u^{*}, u\right)=0$. They can be shown to lie on a circle which
converges to a circle, respectively, a point, as $x \rightarrow a$ or $x \rightarrow b$ (see Problem 9.9).

Before proceeding, let us shed some light on the number of possible boundary conditions. Suppose $\tau$ is l.c. at $a$ and let $u_{1}, u_{2}$ be two solutions of $\tau u=0$ with $W\left(u_{1}, u_{2}\right)=1$. Abbreviate

$$
\begin{equation*}
B C_{x}^{j}(f)=W_{x}\left(u_{j}, f\right), \quad f \in \mathfrak{D}(\tau) \tag{9.22}
\end{equation*}
$$

Let $v$ be as in Theorem 9.6. Then, using Lemma 9.5, it is not hard to see that

$$
\begin{equation*}
W_{a}(v, f)=0 \quad \Leftrightarrow \quad \cos (\alpha) B C_{a}^{1}(f)-\sin (\alpha) B C_{a}^{2}(f)=0 \tag{9.23}
\end{equation*}
$$

where $\tan (\alpha)=-\frac{B C_{a}^{1}(v)}{B C_{a}^{2}(v)}$. Hence all possible boundary conditions can be parametrized by $\alpha \in[0, \pi)$. If $\tau$ is regular at $a$ and if we choose $u_{1}(a)=$ $\left(p u_{2}^{\prime}\right)(a)=1$ and $\left(p u_{1}^{\prime}\right)(a)=u_{2}(a)=0$, then

$$
\begin{equation*}
B C_{a}^{1}(f)=f(a), \quad B C_{a}^{2}(f)=\left(p f^{\prime}\right)(a) \tag{9.24}
\end{equation*}
$$

and the boundary condition takes the simple form

$$
\begin{equation*}
\sin (\alpha)\left(p f^{\prime}\right)(a)-\cos (\alpha) f(a)=0 \tag{9.25}
\end{equation*}
$$

The most common choice of $\alpha=0$ is known as the Dirichlet boundary condition $f(a)=0$. The choice $\alpha=\pi / 2$ is known as the Neumann boundary condition $\left(p f^{\prime}\right)(a)=0$.

Finally, note that if $\tau$ is l.c. at both $a$ and $b$, then Theorem 9.6 does not give all possible self-adjoint extensions. For example, one could also choose

$$
\begin{equation*}
B C_{a}^{1}(f)=\mathrm{e}^{\mathrm{i} \alpha} B C_{b}^{1}(f), \quad B C_{a}^{2}(f)=\mathrm{e}^{\mathrm{i} \alpha} B C_{b}^{2}(f) \tag{9.26}
\end{equation*}
$$

The case $\alpha=0$ gives rise to periodic boundary conditions in the regular case.

Next we want to compute the resolvent of $A$.
Lemma 9.7. Suppose $z \in \rho(A)$. Then there exists a solution $u_{a}(z, x)$ of $(\tau-z) u=g$ which is in $L^{2}((a, c), r d x)$ and which satisfies the boundary condition at a if $\tau$ is l.c. at a. Similarly, there exists a solution $u_{b}(z, x)$ with the analogous properties near $b$.

The resolvent of $A$ is given by

$$
\begin{equation*}
(A-z)^{-1} g(x)=\int_{a}^{b} G(z, x, y) g(y) r(y) d y \tag{9.27}
\end{equation*}
$$

where

$$
G(z, x, y)=\frac{1}{W\left(u_{b}(z), u_{a}(z)\right)} \begin{cases}u_{b}(z, x) u_{a}(z, y), & x \geq y,  \tag{9.28}\\ u_{a}(z, x) u_{b}(z, y), & x \leq y\end{cases}
$$

Proof. Let $g \in L_{c}^{2}(I, r d x)$ be real-valued and consider $f=(A-z)^{-1} g \in$ $\mathfrak{D}(A)$. Since $(\tau-z) f=0$ near $a$, respectively, $b$, we obtain $u_{a}(z, x)$ by setting it equal to $f$ near $a$ and using the differential equation to extend it to the rest of $I$. Similarly we obtain $u_{b}$. The only problem is that $u_{a}$ or $u_{b}$ might be identically zero. Hence we need to show that this can be avoided by choosing $g$ properly.

Fix $z$ and let $g$ be supported in $(c, d) \subset I$. Since $(\tau-z) f=g$, we have

$$
\begin{equation*}
f(x)=u_{1}(x)\left(\alpha+\int_{a}^{x} u_{2} g r d y\right)+u_{2}(x)\left(\beta+\int_{x}^{b} u_{1} g r d y\right) \tag{9.29}
\end{equation*}
$$

Near $a(x<c)$ we have $f(x)=\alpha u_{1}(x)+\tilde{\beta} u_{2}(x)$ and near $b(x>d)$ we have $f(x)=\tilde{\alpha} u_{1}(x)+\beta u_{2}(x)$, where $\tilde{\alpha}=\alpha+\int_{a}^{b} u_{2} g r d y$ and $\tilde{\beta}=\beta+\int_{a}^{b} u_{1} g r d y$. If $f$ vanishes identically near both $a$ and $b$, we must have $\alpha=\beta=\tilde{\alpha}=\tilde{\beta}=0$ and thus $\alpha=\beta=0$ and $\int_{a}^{b} u_{j}(y) g(y) r(y) d y=0, j=1,2$. This case can be avoided by choosing a suitable $g$ and hence there is at least one solution, say $u_{b}(z)$.

Now choose $u_{1}=u_{b}$ and consider the behavior near $b$. If $u_{2}$ is not square integrable on $(d, b)$, we must have $\beta=0$ since $\beta u_{2}=f-\tilde{\alpha} u_{b}$ is. If $u_{2}$ is square integrable, we can find two functions in $\mathfrak{D}(\tau)$ which coincide with $u_{b}$ and $u_{2}$ near $b$. Since $W\left(u_{b}, u_{2}\right)=1$, we see that $\tau$ is l.c. at $a$ and hence $0=W_{b}\left(u_{b}, f\right)=W_{b}\left(u_{b}, \tilde{\alpha} u_{b}+\beta u_{2}\right)=\beta$. Thus $\beta=0$ in both cases and we have

$$
f(x)=u_{b}(x)\left(\alpha+\int_{a}^{x} u_{2} g r d y\right)+u_{2}(x) \int_{x}^{b} u_{b} g r d y
$$

Now choosing $g$ such that $\int_{a}^{b} u_{b} g r d y \neq 0$, we infer the existence of $u_{a}(z)$. Choosing $u_{2}=u_{a}$ and arguing as before, we see $\alpha=0$ and hence

$$
\begin{aligned}
f(x) & =u_{b}(x) \int_{a}^{x} u_{a}(y) g(y) r(y) d y+u_{a}(x) \int_{x}^{b} u_{b}(y) g(y) r(y) d y \\
& =\int_{a}^{b} G(z, x, y) g(y) r(y) d y
\end{aligned}
$$

for any $g \in L_{c}^{2}(I, r d x)$. Since this set is dense, the claim follows.

Example. If $\tau$ is regular at $a$ with a boundary condition as in the previous example, we can choose $u_{a}(z, x)$ to be the solution corresponding to the initial conditions $\left(u_{a}(z, a),\left(p u_{a}^{\prime}\right)(z, a)\right)=(\sin (\alpha), \cos (\alpha))$. In particular, $u_{a}(z, x)$ exists for all $z \in \mathbb{C}$.

If $\tau$ is regular at both $a$ and $b$, there is a corresponding solution $u_{b}(z, x)$, again for all $z$. So the only values of $z$ for which $(A-z)^{-1}$ does not exist must be those with $W\left(u_{b}(z), u_{a}(z)\right)=0$. However, in this case $u_{a}(z, x)$
and $u_{b}(z, x)$ are linearly dependent and $u_{a}(z, x)=\gamma u_{b}(z, x)$ satisfies both boundary conditions. That is, $z$ is an eigenvalue in this case.

In particular, regular operators have pure point spectrum. We will see in Theorem 9.10 below that this holds for any operator which is l.c. at both endpoints.

In the previous example $u_{a}(z, x)$ is holomorphic with respect to $z$ and satisfies $u_{a}(z, x)^{*}=u_{a}\left(z^{*}, x\right)$ (since it corresponds to real initial conditions and our differential equation has real coefficients). In general we have:

Lemma 9.8. Suppose $z \in \rho(A)$. Then $u_{a}(z, x)$ from the previous lemma can be chosen locally holomorphic with respect to $z$ such that

$$
\begin{equation*}
u_{a}(z, x)^{*}=u_{a}\left(z^{*}, x\right) \tag{9.30}
\end{equation*}
$$

and similarly for $u_{b}(z, x)$.
Proof. Since this is a local property near $a$, we can assume $b$ is regular and choose $u_{b}(z, x)$ such that $\left(u_{b}(z, b),\left(p u_{b}^{\prime}\right)(z, b)\right)=(\sin (\beta),-\cos (\beta))$ as in the example above. In addition, choose a second solution $v_{b}(z, x)$ such that $\left(v_{b}(z, b),\left(p v_{b}^{\prime}\right)(z, b)\right)=(\cos (\beta), \sin (\beta))$ and observe $W\left(u_{b}(z), v_{b}(z)\right)=1$. If $z \in \rho(A), z$ is no eigenvalue and hence $u_{a}(z, x)$ cannot be a multiple of $u_{b}(z, x)$. Thus we can set

$$
u_{a}(z, x)=v_{b}(z, x)+m(z) u_{b}(z, x)
$$

and it remains to show that $m(z)$ is holomorphic with $m(z)^{*}=m\left(z^{*}\right)$.
Choosing $h$ with compact support in $(a, c)$ and $g$ with support in $(c, b)$, we have

$$
\begin{aligned}
\left\langle h,(A-z)^{-1} g\right\rangle & =\left\langle h, u_{a}(z)\right\rangle\left\langle g^{*}, u_{b}(z)\right\rangle \\
& =\left(\left\langle h, v_{b}(z)\right\rangle+m(z)\left\langle h, u_{b}(z)\right\rangle\right)\left\langle g^{*}, u_{b}(z)\right\rangle
\end{aligned}
$$

(with a slight abuse of notation since $u_{b}, v_{b}$ might not be square integrable). Choosing (real-valued) functions $h$ and $g$ such that $\left\langle h, u_{b}(z)\right\rangle\left\langle g^{*}, u_{b}(z)\right\rangle \neq 0$, we can solve for $m(z)$ :

$$
m(z)=\frac{\left\langle h,(A-z)^{-1} g\right\rangle-\left\langle h, v_{b}(z)\right\rangle\left\langle g^{*}, u_{b}(z)\right\rangle}{\left\langle h, u_{b}(z)\right\rangle\left\langle g^{*}, u_{b}(z)\right\rangle} .
$$

This finishes the proof.
Example. We already know that $\tau=-\frac{d^{2}}{d x^{2}}$ on $I=(-\infty, \infty)$ gives rise to the free Schrödinger operator $H_{0}$. Furthermore,

$$
\begin{equation*}
u_{ \pm}(z, x)=\mathrm{e}^{\mp \sqrt{-z} x}, \quad z \in \mathbb{C} \tag{9.31}
\end{equation*}
$$

are two linearly independent solutions (for $z \neq 0$ ) and since $\operatorname{Re}(\sqrt{-z})>0$ for $z \in \mathbb{C} \backslash[0, \infty)$, there is precisely one solution (up to a constant multiple)
which is square integrable near $\pm \infty$, namely $u_{ \pm}$. In particular, the only choice for $u_{a}$ is $u_{-}$and for $u_{b}$ is $u_{+}$and we get

$$
\begin{equation*}
G(z, x, y)=\frac{1}{2 \sqrt{-z}} \mathrm{e}^{-\sqrt{-z}|x-y|} \tag{9.32}
\end{equation*}
$$

which we already found in Section 7.4.
$\diamond$
If, as in the previous example, there is only one square integrable solution, there is no choice for $G(z, x, y)$. But since different boundary conditions must give rise to different resolvents, there is no room for boundary conditions in this case. This indicates a connection between our l.c., l.p. distinction and square integrability of solutions.

Theorem 9.9 (Weyl alternative). The operator $\tau$ is l.c. at a if and only if for one $z_{0} \in \mathbb{C}$ all solutions of $\left(\tau-z_{0}\right) u=0$ are square integrable near $a$. This then holds for all $z \in \mathbb{C}$ and similarly for $b$.

Proof. If all solutions are square integrable near $a, \tau$ is l.c. at $a$ since the Wronskian of two linearly independent solutions does not vanish.

Conversely, take two functions $v, \tilde{v} \in \mathfrak{D}(\tau)$ with $W_{a}(v, \tilde{v}) \neq 0$. By considering real and imaginary parts, it is no restriction to assume that $v$ and $\tilde{v}$ are real-valued. Thus they give rise to two different self-adjoint operators $A$ and $\tilde{A}$ (choose any fixed $w$ for the other endpoint). Let $u_{a}$ and $\tilde{u}_{a}$ be the corresponding solutions from above. Then $W\left(u_{a}, \tilde{u}_{a}\right) \neq 0$ (since otherwise $A=\tilde{A}$ by Lemma 9.5 ) and thus there are two linearly independent solutions which are square integrable near $a$. Since any other solution can be written as a linear combination of those two, every solution is square integrable near $a$.

It remains to show that all solutions of $(\tau-z) u=0$ for all $z \in \mathbb{C}$ are square integrable near $a$ if $\tau$ is l.c. at $a$. In fact, the above argument ensures this for every $z \in \rho(A) \cap \rho(\tilde{A})$, that is, at least for all $z \in \mathbb{C} \backslash \mathbb{R}$.

Suppose $(\tau-z) u=0$ and choose two linearly independent solutions $u_{j}$, $j=1,2$, of $\left(\tau-z_{0}\right) u=0$ with $W\left(u_{1}, u_{2}\right)=1$. Using $\left(\tau-z_{0}\right) u=\left(z-z_{0}\right) u$ and (9.10), we have ( $a<c<x<b$ )
$u(x)=\alpha u_{1}(x)+\beta u_{2}(x)+\left(z-z_{0}\right) \int_{c}^{x}\left(u_{1}(x) u_{2}(y)-u_{1}(y) u_{2}(x)\right) u(y) r(y) d y$.
Since $u_{j} \in L^{2}((c, b), r d x)$, we can find a constant $M \geq 0$ such that

$$
\int_{c}^{b}\left|u_{1,2}(y)\right|^{2} r(y) d y \leq M .
$$

Now choose $c$ close to $b$ such that $\left|z-z_{0}\right| M^{2} \leq 1 / 4$. Next, estimating the integral using Cauchy-Schwarz gives

$$
\begin{aligned}
& \left|\int_{c}^{x}\left(u_{1}(x) u_{2}(y)-u_{1}(y) u_{2}(x)\right) u(y) r(y) d y\right|^{2} \\
& \quad \leq \int_{c}^{x}\left|u_{1}(x) u_{2}(y)-u_{1}(y) u_{2}(x)\right|^{2} r(y) d y \int_{c}^{x}|u(y)|^{2} r(y) d y \\
& \quad \leq M\left(\left|u_{1}(x)\right|^{2}+\left|u_{2}(x)\right|^{2}\right) \int_{c}^{x}|u(y)|^{2} r(y) d y
\end{aligned}
$$

and hence

$$
\begin{aligned}
\int_{c}^{x}|u(y)|^{2} r(y) d y & \leq\left(|\alpha|^{2}+|\beta|^{2}\right) M+2\left|z-z_{0}\right| M^{2} \int_{c}^{x}|u(y)|^{2} r(y) d y \\
& \leq\left(|\alpha|^{2}+|\beta|^{2}\right) M+\frac{1}{2} \int_{c}^{x}|u(y)|^{2} r(y) d y
\end{aligned}
$$

Thus

$$
\int_{c}^{x}|u(y)|^{2} r(y) d y \leq 2\left(|\alpha|^{2}+|\beta|^{2}\right) M
$$

and since $u \in A C_{l o c}(I)$, we have $u \in L^{2}((c, b), r d x)$ for every $c \in(a, b)$.
Now we turn to the investigation of the spectrum of $A$. If $\tau$ is l.c. at both endpoints, then the spectrum of $A$ is very simple

Theorem 9.10. If $\tau$ is l.c. at both endpoints, then the resolvent is a HilbertSchmidt operator; that is,

$$
\begin{equation*}
\int_{a}^{b} \int_{a}^{b}|G(z, x, y)|^{2} r(y) d y r(x) d x<\infty . \tag{9.33}
\end{equation*}
$$

In particular, the spectrum of any self-adjoint extensions is purely discrete and the eigenfunctions (which are simple) form an orthonormal basis.

Proof. This follows from the estimate

$$
\begin{aligned}
& \int_{a}^{b}\left(\int_{a}^{x}\left|u_{b}(x) u_{a}(y)\right|^{2} r(y) d y+\int_{x}^{b}\left|u_{b}(y) u_{a}(x)\right|^{2} r(y) d y\right) r(x) d x \\
& \quad \leq 2 \int_{a}^{b}\left|u_{a}(y)\right|^{2} r(y) d y \int_{a}^{b}\left|u_{b}(y)\right|^{2} r(y) d y,
\end{aligned}
$$

which shows that the resolvent is Hilbert-Schmidt and hence compact.
Note that all eigenvalues are simple. If $\tau$ is l.p. at one endpoint, this is clear, since there is at most one solution of $(\tau-\lambda) u=0$ which is square integrable near this endpoint. If $\tau$ is l.c., this also follows since the fact that two solutions of $(\tau-\lambda) u=0$ satisfy the same boundary condition implies that their Wronskian vanishes.

If $\tau$ is not l.c., the situation is more complicated and we can only say something about the essential spectrum.

Theorem 9.11. All self-adjoint extensions have the same essential spectrum. Moreover, if $A_{a c}$ and $A_{c b}$ are self-adjoint extensions of $\tau$ restricted to $(a, c)$ and $(c, b)$ (for any $c \in I$ ), then

$$
\begin{equation*}
\sigma_{\text {ess }}(A)=\sigma_{\text {ess }}\left(A_{a c}\right) \cup \sigma_{\text {ess }}\left(A_{c b}\right) . \tag{9.34}
\end{equation*}
$$

Proof. Since $(\tau-\mathrm{i}) u=0$ has two linearly independent solutions, the defect indices are at most two (they are zero if $\tau$ is l.p. at both endpoints, one if $\tau$ is l.c. at one and l.p. at the other endpoint, and two if $\tau$ is l.c. at both endpoints). Hence the first claim follows from Theorem 6.20.

For the second claim restrict $\tau$ to the functions with compact support in $(a, c) \cup(c, d)$. Then, this operator is the orthogonal sum of the operators $A_{0, a c}$ and $A_{0, c b}$. Hence the same is true for the adjoints and hence the defect indices of $A_{0, a c} \oplus A_{0, c b}$ are at most four. Now note that $A$ and $A_{a c} \oplus A_{c b}$ are both self-adjoint extensions of this operator. Thus the second claim also follows from Theorem 6.20.

In particular, this result implies that for the essential spectrum only the behaviour near the endpoints $a$ and $b$ is relevant.

Another useful result to determine if $q$ is relatively compact is the following:

Lemma 9.12. Suppose $k \in L_{\text {loc }}^{2}((a, b), r d x)$. Then $k R_{A}(z)$ is HilbertSchmidt if and only if

$$
\begin{equation*}
\left\|k R_{A}(z)\right\|_{2}^{2}=\frac{1}{\operatorname{Im}(z)} \int_{a}^{b}|k(x)|^{2} \operatorname{Im}(G(z, x, x)) r(x) d x \tag{9.35}
\end{equation*}
$$

is finite.
Proof. From the first resolvent formula we have

$$
G(z, x, y)-G\left(z^{\prime}, x, y\right)=\left(z-z^{\prime}\right) \int_{a}^{b} G(z, x, t) G\left(z^{\prime}, t, y\right) r(t) d t .
$$

Setting $x=y$ and $z^{\prime}=z^{*}$, we obtain

$$
\begin{equation*}
\operatorname{Im}(G(z, x, x))=\operatorname{Im}(z) \int_{a}^{b}|G(z, x, t)|^{2} r(t) d t \tag{9.36}
\end{equation*}
$$

Using this last formula to compute the Hilbert-Schmidt norm proves the lemma.

Problem 9.5. Compute the spectrum and the resolvent of $\tau=-\frac{d^{2}}{d x^{2}}, I=$ $(0, \infty)$ defined on $\mathfrak{D}(A)=\{f \in \mathfrak{D}(\tau) \mid f(0)=0\}$.

Problem 9.6. Suppose $\tau$ is given on ( $a, \infty$ ), where $a$ is a regular endpoint. Suppose there are two solutions $u_{ \pm}$of $\tau u=z u$ satisfying $r(x)^{1 / 2}\left|u_{ \pm}(x)\right| \leq$ $C \mathrm{e}^{\mp \alpha x}$ for some $C, \alpha>0$. Then $z$ is not in the essential spectrum of any selfadjoint operator corresponding to $\tau$. (Hint: You can take any self-adjoint extension, say the one for which $u_{a}=u_{-}$and $u_{b}=u_{+}$. Write down what you expect the resolvent to be and show that it is a bounded operator by comparison with the resolvent from the previous problem.)
Problem 9.7. Suppose $a$ is regular and $\lim _{x \rightarrow b} q(x) / r(x)=\infty$. Show that $\sigma_{\text {ess }}(A)=\emptyset$ for every self-adjoint extension. (Hint: Fix some positive constant $n$ and choose $c \in(a, b)$ such that $q(x) / r(x) \geq n$ in $(c, b)$ and use Theorem 9.11.)

Problem 9.8 (Approximation by regular operators). Fix functions $v, w \in$ $\mathfrak{D}(\tau)$ as in Theorem 9.6. Pick $I_{m}=\left(c_{m}, d_{m}\right)$ with $c_{m} \downarrow a, d_{m} \uparrow b$ and define

$$
\begin{aligned}
A_{m}: \mathfrak{D}\left(A_{m}\right) & \rightarrow L^{2}\left(I_{m}, r d r\right), \\
f & \mapsto \tau f
\end{aligned}
$$

where

$$
\begin{aligned}
\mathfrak{D}\left(A_{m}\right)=\left\{f \in L^{2}\left(I_{m}, r d r\right) \mid\right. & f, p f^{\prime} \in A C\left(I_{m}\right), \tau f \in L^{2}\left(I_{m}, r d r\right), \\
& \left.W_{c_{m}}(v, f)=W_{d_{m}}(w, f)=0\right\} .
\end{aligned}
$$

Then $A_{m}$ converges to $A$ in the strong resolvent sense as $m \rightarrow \infty$. (Hint: Lemma 6.36.)
Problem 9.9 (Weyl circles). Fix $z \in \mathbb{C} \backslash \mathbb{R}$ and $c \in(a, b)$. Introduce

$$
[u]_{x}=\frac{W\left(u, u^{*}\right)_{x}}{z-z^{*}} \in \mathbb{R}
$$

and use (9.4) to show that

$$
[u]_{x}=[u]_{c}+\int_{c}^{x}|u(y)|^{2} r(y) d y, \quad(\tau-z) u=0 .
$$

Hence $[u]_{x}$ is increasing and exists if and only if $u \in L^{2}((c, b), r d x)$.
Let $u_{1,2}$ be two solutions of $(\tau-z) u=0$ which satisfy $\left[u_{1}\right]_{c}=\left[u_{2}\right]_{c}=0$ and $W\left(u_{1}, u_{2}\right)=1$. Then, all (nonzero) solutions $u$ of $(\tau-z) u=0$ which satisfy $[u]_{b}=0$ can be written as

$$
u=u_{2}+m u_{1}, \quad m \in \mathbb{C},
$$

up to a complex multiple (note $\left[u_{1}\right]_{x}>0$ for $x>c$ ).
Show that

$$
\left[u_{2}+m u_{1}\right]_{x}=\left[u_{1}\right]_{x}\left(|m-M(x)|^{2}-R(x)^{2}\right),
$$

where

$$
M(x)=-\frac{W\left(u_{2}, u_{1}^{*}\right)_{x}}{W\left(u_{1}, u_{1}^{*}\right)_{x}}
$$

and

$$
\begin{aligned}
R(x)^{2} & =\left(\left|W\left(u_{2}, u_{1}^{*}\right)_{x}\right|^{2}+W\left(u_{2}, u_{2}^{*}\right)_{x} W\left(u_{1}, u_{1}^{*}\right)_{x}\right)\left(\left|z-z^{*}\right|\left[u_{1}\right]_{x}\right)^{-2} \\
& =\left(\left|z-z^{*}\right|\left[u_{1}\right]_{x}\right)^{-2} .
\end{aligned}
$$

Hence the numbers $m$ for which $[u]_{x}=0$ lie on a circle which either converges to a circle (if $\lim _{x \rightarrow b} R(x)>0$ ) or to a point (if $\lim _{x \rightarrow b} R(x)=0$ ) as $x \rightarrow b$. Show that $\tau$ is l.c. at $b$ in the first case and l.p. in the second case.

### 9.3. Spectral transformations I

In this section we want to provide some fundamental tools for investigating the spectra of Sturm-Liouville operators and, at the same time, give some nice illustrations of the spectral theorem.
Example. Consider again $\tau=-\frac{d^{2}}{d x^{2}}$ on $I=(-\infty, \infty)$. From Section 7.2 we know that the Fourier transform maps the associated operator $H_{0}$ to the multiplication operator with $p^{2}$ in $L^{2}(\mathbb{R})$. To get multiplication by $\lambda$, as in the spectral theorem, we set $p=\sqrt{\lambda}$ and split the Fourier integral into a positive and negative part, that is,

$$
\begin{equation*}
(U f)(\lambda)=\binom{\int_{\mathbb{R}} \mathrm{e}^{\mathrm{i} \sqrt{\lambda} x} f(x) d x}{\int_{\mathbb{R}} \mathrm{e}^{-\mathrm{i} \sqrt{\lambda} x} f(x) d x}, \quad \lambda \in \sigma\left(H_{0}\right)=[0, \infty) \tag{9.37}
\end{equation*}
$$

Then

$$
\begin{equation*}
U: L^{2}(\mathbb{R}) \rightarrow \bigoplus_{j=1}^{2} L^{2}\left(\mathbb{R}, \frac{\chi_{[0, \infty)}(\lambda)}{2 \sqrt{\lambda}} d \lambda\right) \tag{9.38}
\end{equation*}
$$

is the spectral transformation whose existence is guaranteed by the spectral theorem (Lemma 3.4). Note, however, that the measure is not finite. This can be easily fixed if we replace $\exp ( \pm \mathrm{i} \sqrt{\lambda} x)$ by $\gamma(\lambda) \exp ( \pm \mathrm{i} \sqrt{\lambda} x)$.

Note that in the previous example the kernel $\mathrm{e}^{ \pm \mathrm{i} \sqrt{\lambda} x}$ of the integral transform $U$ is just a pair of linearly independent solutions of the underlying differential equation (though no eigenfunctions, since they are not square integrable).

More generally, if

$$
\begin{equation*}
U: L^{2}(I, r d x) \rightarrow L^{2}(\mathbb{R}, d \mu), \quad f(x) \mapsto \int_{I} u(\lambda, x) f(x) r(x) d x \tag{9.39}
\end{equation*}
$$

is an integral transformation which maps a self-adjoint Sturm-Liouville operator $A$ to multiplication by $\lambda$, then its kernel $u(\lambda, x)$ is a solution of the underlying differential equation. This formally follows from $U A f=\lambda U f$
which implies

$$
\begin{equation*}
0=\int_{I} u(\lambda, x)(\tau-\lambda) f(x) r(x) d x=\int_{I}(\tau-\lambda) u(\lambda, x) f(x) r(x) d x \tag{9.40}
\end{equation*}
$$

and hence $(\tau-\lambda) u(\lambda,)=$.0 .
Lemma 9.13. Suppose

$$
\begin{equation*}
U: L^{2}(I, r d x) \rightarrow \bigoplus_{j=1}^{k} L^{2}\left(\mathbb{R}, d \mu_{j}\right) \tag{9.41}
\end{equation*}
$$

is a spectral mapping as in Lemma 3.4. Then $U$ is of the form

$$
\begin{equation*}
U f(x)=\int_{a}^{b} \underline{u}(\lambda, x) f(x) r(x) d x \tag{9.42}
\end{equation*}
$$

where $\underline{u}(\lambda, x)=\left(u_{1}(\lambda, x), \ldots, u_{k}(\lambda, x)\right)$ is measurable and for a.e. $\lambda$ (with respect to $\mu_{j}$ ) and each $u_{j}(\lambda,$.$) is a solution of \tau u_{j}=\lambda u_{j}$ which satisfies the boundary conditions of $A$ (if any). Here the integral has to be understood as $\int_{a}^{b} d x=\lim _{c \downarrow a, d \uparrow b} \int_{c}^{d} d x$ with limit taken in $\bigoplus_{j} L^{2}\left(\mathbb{R}, d \mu_{j}\right)$.

The inverse is given by

$$
\begin{equation*}
\left(U^{-1} \underline{F}\right)(x)=\sum_{j=1}^{k} \int_{\mathbb{R}} u_{j}(\lambda, x)^{*} F_{j}(\lambda) d \mu_{j}(\lambda) . \tag{9.43}
\end{equation*}
$$

Again the integrals have to be understood as $\int_{\mathbb{R}} d \mu_{j}=\lim _{R \rightarrow \infty} \int_{-R}^{R} d \mu_{j}$ with limits taken in $L^{2}(I, r d x)$.

If the spectral measures are ordered, then the solutions $u_{j}(\lambda), 1 \leq j \leq l$, are linearly independent for a.e. $\lambda$ with respect to $\mu_{l}$. In particular, for ordered spectral measures we always have $k \leq 2$ and even $k=1$ if $\tau$ is l.c. at one endpoint.

Proof. Using $U_{j} R_{A}(z)=\frac{1}{\lambda-z} U_{j}$, we have

$$
U_{j} f(x)=(\lambda-z) U_{j} \int_{a}^{b} G(z, x, y) f(y) r(y) d y
$$

If we restrict $R_{A}(z)$ to a compact interval $[c, d] \subset(a, b)$, then $R_{A}(z) \chi_{[c, d]}$ is Hilbert-Schmidt since $G(z, x, y) \chi_{[c, d]}(y)$ is square integrable over $(a, b) \times$ (a,b). Hence $U_{j} \chi_{[c, d]}=(\lambda-z) U_{j} R_{A}(z) \chi_{[c, d]}$ is Hilbert-Schmidt as well and by Lemma 6.9 there is a corresponding kernel $u_{j}^{[c, d]}(\lambda, y)$ such that

$$
\left(U_{j} \chi_{[c, d]} f\right)(\lambda)=\int_{a}^{b} u_{j}^{[c, d]}(\lambda, x) f(x) r(x) d x .
$$

Now take a larger compact interval $[\hat{c}, \hat{d}] \supseteq[c, d]$. Then the kernels coincide on $[c, d], u_{j}^{[c, d]}(\lambda,)=.u_{j}^{[\hat{c}, \hat{d}]}(\lambda,.) \chi_{[c, d]}$, since we have $U_{j} \chi_{[c, d]}=U_{j} \chi_{[\hat{c}, \hat{d}]} \chi_{[c, d]}$. In particular, there is a kernel $u_{j}(\lambda, x)$ such that

$$
U_{j} f(x)=\int_{a}^{b} u_{j}(\lambda, x) f(x) r(x) d x
$$

for every $f$ with compact support in $(a, b)$. Since functions with compact support are dense and $U_{j}$ is continuous, this formula holds for any $f$ provided the integral is understood as the corresponding limit.

Using the fact that $U$ is unitary, $\langle\underline{F}, U g\rangle=\left\langle U^{-1} \underline{F}, g\right\rangle$, we see

$$
\sum_{j} \int_{\mathbb{R}} F_{j}(\lambda)^{*} \int_{a}^{b} u_{j}(\lambda, x) g(x) r(x) d x=\int_{a}^{b}\left(U^{-1} \underline{F}\right)(x)^{*} g(x) r(x) d x
$$

Interchanging integrals on the right-hand side (which is permitted at least for $g, \underline{F}$ with compact support), the formula for the inverse follows.

Next, from $U_{j} A f=\lambda U_{j} f$ we have

$$
\int_{a}^{b} u_{j}(\lambda, x)(\tau f)(x) r(x) d x=\lambda \int_{a}^{b} u_{j}(\lambda, x) f(x) r(x) d x
$$

for a.e. $\lambda$ and every $f \in \mathfrak{D}\left(A_{0}\right)$. Restricting everything to $[c, d] \subset(a, b)$, the above equation implies $\left.u_{j}(\lambda,)\right|_{.[c, d]} \in \mathfrak{D}\left(A_{c d, 0}^{*}\right)$ and $\left.A_{c d, 0}^{*} u_{j}(\lambda,)\right|_{.[c, d]}=$ $\left.\lambda u_{j}(\lambda,)\right|_{.[c, d]}$. In particular, $u_{j}(\lambda,$.$) is a solution of \tau u_{j}=\lambda u_{j}$. Moreover, if $\tau$ is l.c. near $a$, we can choose $c=a$ and allow all $f \in \mathfrak{D}(\tau)$ which satisfy the boundary condition at $a$ and vanish identically near $b$.

Finally, assume the $\mu_{j}$ are ordered and fix $l \leq k$. Suppose

$$
\sum_{j=1}^{l} c_{j}(\lambda) u_{j}(\lambda, x)=0
$$

Then we have

$$
\sum_{j=1}^{l} c_{j}(\lambda) F_{j}(\lambda)=0, \quad F_{j}=U_{j} f
$$

for every $f$. Since $U$ is surjective, we can prescribe $F_{j}$ arbitrarily on $\sigma\left(\mu_{l}\right)$, e.g., $F_{j}(\lambda)=1$ for $j=j_{0}$ and $F_{j}(\lambda)=0$ otherwise, which shows $c_{j_{0}}(\lambda)=0$. Hence the solutions $u_{j}(\lambda, x), 1 \leq j \leq l$, are linearly independent for $\lambda \in$ $\sigma\left(\mu_{l}\right)$ which shows $k \leq 2$ since there are at most two linearly independent solutions. If $\tau$ is l.c. and $u_{j}(\lambda, x)$ must satisfy the boundary condition, there is only one linearly independent solution and thus $k=1$.

Note that since we can replace $u_{j}(\lambda, x)$ by $\gamma_{j}(\lambda) u_{j}(\lambda, x)$ where $\left|\gamma_{j}(\lambda)\right|=$ 1 , it is no restriction to assume that $u_{j}(\lambda, x)$ is real-valued.

For simplicity we will only pursue the case where one endpoint, say $a$, is regular. The general case can often be reduced to this case and will be postponed until Section 9.6.

We choose a boundary condition

$$
\begin{equation*}
\cos (\alpha) f(a)-\sin (\alpha) p(a) f^{\prime}(a)=0 \tag{9.44}
\end{equation*}
$$

and introduce two solution $s(z, x)$ and $c(z, x)$ of $\tau u=z u$ satisfying the initial conditions

$$
\begin{array}{ll}
s(z, a)=\sin (\alpha), & p(a) s^{\prime}(z, a)=\cos (\alpha) \\
c(z, a)=\cos (\alpha), & p(a) c^{\prime}(z, a)=-\sin (\alpha) \tag{9.45}
\end{array}
$$

Note that $s(z, x)$ is the solution which satisfies the boundary condition at $a$; that is, we can choose $u_{a}(z, x)=s(z, x)$. In fact, if $\tau$ is not regular at $a$ but only l.c., everything below remains valid if one chooses $s(z, x)$ to be a solution satisfying the boundary condition at $a$ and $c(z, x)$ a linearly independent solution with $W(c(z), s(z))=1$.

Moreover, in our previous lemma we have $u_{1}(\lambda, x)=\gamma_{a}(\lambda) s(\lambda, x)$ and using the rescaling $d \mu(\lambda)=\left|\gamma_{a}(\lambda)\right|^{2} d \mu_{a}(\lambda)$ and $\left(U_{1} f\right)(\lambda)=\gamma_{a}(\lambda)(U f)(\lambda)$, we obtain a unitary map

$$
\begin{equation*}
U: L^{2}(I, r d x) \rightarrow L^{2}(\mathbb{R}, d \mu), \quad(U f)(\lambda)=\int_{a}^{b} s(\lambda, x) f(x) r(x) d x \tag{9.46}
\end{equation*}
$$

with inverse

$$
\begin{equation*}
\left(U^{-1} F\right)(x)=\int_{\mathbb{R}} s(\lambda, x) F(\lambda) d \mu(\lambda) \tag{9.47}
\end{equation*}
$$

Note, however, that while this rescaling gets rid of the unknown factor $\gamma_{a}(\lambda)$, it destroys the normalization of the measure $\mu$. For $\mu_{1}$ we know $\mu_{1}(\mathbb{R})$ (if the corresponding vector is normalized), but $\mu$ might not even be bounded! In fact, it turns out that $\mu$ is indeed unbounded.

So up to this point we have our spectral transformation $U$ which maps $A$ to multiplication by $\lambda$, but we know nothing about the measure $\mu$. Furthermore, the measure $\mu$ is the object of desire since it contains all the spectral information of $A$. So our next aim must be to compute $\mu$. If $A$ has only pure point spectrum (i.e., only eigenvalues), this is straightforward as the following example shows.

Example. Suppose $E \in \sigma_{p}(A)$ is an eigenvalue. Then $s(E, x)$ is the corresponding eigenfunction and the same is true for $S_{E}(\lambda)=(U s(E))(\lambda)$. In particular, $\chi_{\{E\}}(A) s(E, x)=s(E, x)$ shows $S_{E}(\lambda)=\left(U \chi_{\{E\}}(A) s(E)\right)(\lambda)=$ $\chi_{\{E\}}(\lambda) S_{E}(\lambda)$; that is,

$$
S_{E}(\lambda)= \begin{cases}\|s(E)\|^{2}, & \lambda=E  \tag{9.48}\\ 0, & \lambda \neq 0\end{cases}
$$

Moreover, since $U$ is unitary, we have

$$
\begin{equation*}
\|s(E)\|^{2}=\int_{a}^{b} s(E, x)^{2} r(x) d x=\int_{\mathbb{R}} S_{E}(\lambda)^{2} d \mu(\lambda)=\|s(E)\|^{4} \mu(\{E\}) ; \tag{9.49}
\end{equation*}
$$

that is, $\mu(\{E\})=\|s(E)\|^{-2}$. In particular, if $A$ has pure point spectrum (e.g., if $\tau$ is limit circle at both endpoints), we have

$$
\begin{equation*}
d \mu(\lambda)=\sum_{j=1}^{\infty} \frac{1}{\left\|s\left(E_{j}\right)\right\|^{2}} d \Theta\left(\lambda-E_{j}\right), \quad \sigma_{p}(A)=\left\{E_{j}\right\}_{j=1}^{\infty} \tag{9.50}
\end{equation*}
$$

where $d \Theta$ is the Dirac measure centered at 0 . For arbitrary $A$, the above formula holds at least for the pure point part $\mu_{p p}$.

In the general case we have to work a bit harder. Since $c(z, x)$ and $s(z, x)$ are linearly independent solutions,

$$
\begin{equation*}
W(c(z), s(z))=1, \tag{9.51}
\end{equation*}
$$

we can write $u_{b}(z, x)=\gamma_{b}(z)\left(c(z, x)+m_{b}(z) s(z, x)\right)$, where

$$
\begin{equation*}
m_{b}(z)=\frac{\cos (\alpha) p(a) u_{b}^{\prime}(z, a)+\sin (\alpha) u_{b}(z, a)}{\cos (\alpha) u_{b}(z, a)-\sin (\alpha) p(a) u_{b}^{\prime}(z, a)}, \quad z \in \rho(A), \tag{9.52}
\end{equation*}
$$

is known as the Weyl-Titchmarsh $m$-function. Note that $m_{b}(z)$ is holomorphic in $\rho(A)$ and that

$$
\begin{equation*}
m_{b}(z)^{*}=m_{b}\left(z^{*}\right) \tag{9.53}
\end{equation*}
$$

since the same is true for $u_{b}(z, x)$ (the denominator in (9.52) only vanishes if $u_{b}(z, x)$ satisfies the boundary condition at $a$, that is, if $z$ is an eigenvalue). Moreover, the constant $\gamma_{b}(z)$ is of no importance and can be chosen equal to one,

$$
\begin{equation*}
u_{b}(z, x)=c(z, x)+m_{b}(z) s(z, x) . \tag{9.54}
\end{equation*}
$$

Lemma 9.14. The Weyl m-function is a Herglotz function and satisfies

$$
\begin{equation*}
\operatorname{Im}\left(m_{b}(z)\right)=\operatorname{Im}(z) \int_{a}^{b}\left|u_{b}(z, x)\right|^{2} r(x) d x \tag{9.55}
\end{equation*}
$$

where $u_{b}(z, x)$ is normalized as in (9.54).
Proof. Given two solutions $u(x), v(x)$ of $\tau u=z u, \tau v=\hat{z} v$, respectively, it is straightforward to check

$$
(\hat{z}-z) \int_{a}^{x} u(y) v(y) r(y) d y=W_{x}(u, v)-W_{a}(u, v)
$$

(clearly it is true for $x=a$; now differentiate with respect to $x$ ). Now choose $u(x)=u_{b}(z, x)$ and $v(x)=u_{b}(z, x)^{*}=u_{b}\left(z^{*}, x\right)$,

$$
-2 \operatorname{Im}(z) \int_{a}^{x}\left|u_{b}(z, y)\right|^{2} r(y) d y=W_{x}\left(u_{b}(z), u_{b}(z)^{*}\right)-2 \operatorname{Im}\left(m_{b}(z)\right),
$$

and observe that $W_{x}\left(u_{b}, u_{b}^{*}\right)$ vanishes as $x \uparrow b$, since both $u_{b}$ and $u_{b}^{*}$ are in $\mathfrak{D}(\tau)$ near $b$.

Lemma 9.15. Let

$$
G(z, x, y)= \begin{cases}s(z, x) u_{b}(z, y), & y \geq x  \tag{9.56}\\ s(z, y) u_{b}(z, x), & y \leq x\end{cases}
$$

be the Green function of $A$. Then

$$
\begin{equation*}
(U G(z, x, .))(\lambda)=\frac{s(\lambda, x)}{\lambda-z} \quad \text { and } \quad\left(U p(x) \partial_{x} G(z, x, .)\right)(\lambda)=\frac{p(x) s^{\prime}(\lambda, x)}{\lambda-z} \tag{9.57}
\end{equation*}
$$

for every $x \in(a, b)$ and every $z \in \rho(A)$.
Proof. First of all note that $G(z, x,.) \in L^{2}((a, b), r d x)$ for every $x \in(a, b)$ and $z \in \rho(A)$. Moreover, from $R_{A}(z) f=U^{-1} \frac{1}{\lambda-z} U f$ we have

$$
\begin{equation*}
\int_{a}^{b} G(z, x, y) f(y) r(y) d y=\int_{\mathbb{R}} \frac{s(\lambda, x) F(\lambda)}{\lambda-z} d \mu(\lambda) \tag{9.58}
\end{equation*}
$$

where $F=U f$. Here equality is to be understood in $L^{2}$, that is, for a.e. $x$. However, the left-hand side is continuous with respect to $x$ and so is the right-hand side, at least if $F$ has compact support. Since this set is dense, the first equality follows. Similarly, the second follows after differentiating (9.58) with respect to $x$.

Corollary 9.16. We have

$$
\begin{equation*}
\left(U u_{b}(z)\right)(\lambda)=\frac{1}{\lambda-z}, \tag{9.59}
\end{equation*}
$$

where $u_{b}(z, x)$ is normalized as in (9.54).
Proof. Choosing $x=a$ in the lemma, we obtain the claim from the first identity if $\sin (\alpha) \neq 0$ and from the second if $\cos (\alpha) \neq 0$.

Now combining Lemma 9.14 and Corollary 9.16, we infer from unitarity of $U$ that

$$
\begin{equation*}
\operatorname{Im}\left(m_{b}(z)\right)=\operatorname{Im}(z) \int_{a}^{b}\left|u_{b}(z, x)\right|^{2} r(x) d x=\operatorname{Im}(z) \int_{\mathbb{R}} \frac{1}{|\lambda-z|^{2}} d \mu(\lambda) \tag{9.60}
\end{equation*}
$$

and since a holomorphic function is determined up to a real constant by its imaginary part, we obtain

Theorem 9.17. The Weyl m-function is given by

$$
\begin{equation*}
m_{b}(z)=d+\int_{\mathbb{R}}\left(\frac{1}{\lambda-z}-\frac{\lambda}{1+\lambda^{2}}\right) d \mu(\lambda), \quad d \in \mathbb{R} \tag{9.61}
\end{equation*}
$$

and

$$
\begin{equation*}
d=\operatorname{Re}\left(m_{b}(\mathrm{i})\right), \quad \int_{\mathbb{R}} \frac{1}{1+\lambda^{2}} d \mu(\lambda)=\operatorname{Im}\left(m_{b}(\mathrm{i})\right)<\infty \tag{9.62}
\end{equation*}
$$

Moreover, $\mu$ is given by the Stieltjes inversion formula

$$
\begin{equation*}
\mu(\lambda)=\lim _{\delta \downarrow 0} \lim _{\varepsilon \downarrow 0} \frac{1}{\pi} \int_{\delta}^{\lambda+\delta} \operatorname{Im}\left(m_{b}(\lambda+\mathrm{i} \varepsilon)\right) d \lambda, \tag{9.63}
\end{equation*}
$$

where

$$
\begin{equation*}
\operatorname{Im}\left(m_{b}(\lambda+\mathrm{i} \varepsilon)\right)=\varepsilon \int_{a}^{b}\left|u_{b}(\lambda+\mathrm{i} \varepsilon, x)\right|^{2} r(x) d x . \tag{9.64}
\end{equation*}
$$

Proof. Choosing $z=\mathrm{i}$ in (9.60) shows (9.62) and hence the right-hand side of (9.61) is a well-defined holomorphic function in $\mathbb{C} \backslash \mathbb{R}$. By

$$
\operatorname{Im}\left(\frac{1}{\lambda-z}-\frac{\lambda}{1+\lambda^{2}}\right)=\frac{\operatorname{Im}(z)}{|\lambda-z|^{2}}
$$

its imaginary part coincides with that of $m_{b}(z)$ and hence equality follows. The Stieltjes inversion formula follows as in the case where the measure is bounded.

Example. Consider $\tau=-\frac{d^{2}}{d x^{2}}$ on $I=(0, \infty)$. Then

$$
\begin{equation*}
c(z, x)=\cos (\alpha) \cos (\sqrt{z} x)-\frac{\sin (\alpha)}{\sqrt{z}} \sin (\sqrt{z} x) \tag{9.65}
\end{equation*}
$$

and

$$
\begin{equation*}
s(z, x)=\sin (\alpha) \cos (\sqrt{z} x)+\frac{\cos (\alpha)}{\sqrt{z}} \sin (\sqrt{z} x) . \tag{9.66}
\end{equation*}
$$

Moreover,

$$
\begin{equation*}
u_{b}(z, x)=u_{b}(z, 0) \mathrm{e}^{-\sqrt{-z} x} \tag{9.67}
\end{equation*}
$$

and thus

$$
\begin{equation*}
m_{b}(z)=\frac{\sin (\alpha)-\sqrt{-z} \cos (\alpha)}{\cos (\alpha)+\sqrt{-z} \sin (\alpha)}, \tag{9.68}
\end{equation*}
$$

respectively,

$$
\begin{equation*}
d \mu(\lambda)=\frac{\sqrt{\lambda}}{\pi\left(\cos (\alpha)^{2}+\lambda \sin (\alpha)^{2}\right)} d \lambda . \tag{9.69}
\end{equation*}
$$

Note that if $\alpha \neq 0$, we even have $\int \frac{1}{|\lambda-z|} d \mu(\lambda)<0$ in the previous example and hence

$$
\begin{equation*}
m_{b}(z)=-\cot (\alpha)+\int_{\mathbb{R}} \frac{1}{\lambda-z} d \mu(\lambda) \tag{9.70}
\end{equation*}
$$

in this case (the factor $-\cot (\alpha)$ follows by considering the limit $|z| \rightarrow \infty$ of both sides). Formally this even follows in the general case by choosing $x=a$ in $u_{b}(z, x)=\left(U^{-1} \frac{1}{\lambda-z}\right)(x)$; however, since we know equality only for
a.e. $x$, a more careful analysis is needed. We will address this problem in the next section.

Problem 9.10. Show

$$
\begin{equation*}
m_{b, \alpha}(z)=\frac{\cos (\alpha-\beta) m_{b, \beta}(z)+\sin (\alpha-\beta)}{\cos (\alpha-\beta)-\sin (\alpha-\beta) m_{b, \beta}(z)} \tag{9.71}
\end{equation*}
$$

(Hint: The case $\beta=0$ is (9.52).)
Problem 9.11. Let $\phi_{0}(x), \theta_{0}(x)$ be two real-valued solutions of $\tau u=\lambda_{0} u$ for some fixed $\lambda_{0} \in \mathbb{R}$ such that $W\left(\theta_{0}, \phi_{0}\right)=1$. We will call $\tau$ quasi-regular at a if the limits

$$
\begin{equation*}
\lim _{x \rightarrow a} W_{x}\left(\phi_{0}, u(z)\right), \quad \lim _{x \rightarrow a} W_{x}\left(\theta_{0}, u(z)\right) \tag{9.72}
\end{equation*}
$$

exist for every solution $u(z)$ of $\tau u=z u$. Show that this definition is independent of $\lambda_{0}$ (Hint: Plücker's identity). Show that $\tau$ is quasi-regular at a if it is l.c. at a.

Introduce

$$
\begin{align*}
& \phi(z, x)=W_{a}\left(c(z), \phi_{0}\right) s(z, x)-W_{a}\left(s(z), \phi_{0}\right) c(z, x), \\
& \theta(z, x)=W_{a}\left(s(z), \theta_{0}\right) c(z, x)-W_{a}\left(c(z), \theta_{0}\right) s(z, x), \tag{9.73}
\end{align*}
$$

where $c(z, x)$ and $s(z, x)$ are chosen with respect to some base point $c \in(a, b)$, and a singular Weyl m-function $M_{b}(z)$ such that

$$
\begin{equation*}
\psi(z, x)=\theta(z, x)+M_{b}(z) \phi(z, x) \in L^{2}(c, b) . \tag{9.74}
\end{equation*}
$$

Show that all claims from this section still hold true in this case for the operator associated with the boundary condition $W_{a}\left(\phi_{0}, f\right)=0$ if $\tau$ is l.c. at $a$.

### 9.4. Inverse spectral theory

In this section we want to show that the Weyl $m$-function (respectively, the corresponding spectral measure) uniquely determines the operator. For simplicity we only consider the case $p=r \equiv 1$.

We begin with some asymptotics for large $z$ away from the spectrum. We recall that $\sqrt{z}$ always denotes the branch with $\arg (z) \in(-\pi, \pi]$. We will write $c(z, x)=c_{\alpha}(z, x)$ and $s(z, x)=s_{\alpha}(z, x)$ to display the dependence on $\alpha$ whenever necessary.

We first observe (Problem 9.12)

Lemma 9.18. For $\alpha=0$ we have

$$
\begin{align*}
& c_{0}(z, x)=\cosh (\sqrt{-z}(x-a))+O\left(\frac{1}{\sqrt{-z}} \mathrm{e}^{\sqrt{-z}(x-a)}\right), \\
& s_{0}(z, x)=\frac{1}{\sqrt{-z}} \sinh (\sqrt{-z}(x-a))+O\left(\frac{1}{z} \mathrm{e}^{\sqrt{-z}(x-a)}\right), \tag{9.75}
\end{align*}
$$

uniformly for $x \in(a, c)$ as $|z| \rightarrow \infty$.
Note that for $z \in \mathbb{C} \backslash[0, \infty)$ this can be written as

$$
\begin{align*}
& c_{0}(z, x)=\frac{1}{2} \mathrm{e}^{\sqrt{-z}(x-a)}\left(1+O\left(\frac{1}{\sqrt{-z}}\right)\right) \\
& s_{0}(z, x)=\frac{1}{2 \sqrt{-z}} \mathrm{e}^{\sqrt{-z}(x-a)}\left(1+O\left(\frac{1}{z}\right)\right), \tag{9.76}
\end{align*}
$$

for $\operatorname{Im}(z) \rightarrow \infty$ and for $z=\lambda \in[0, \infty)$ we have

$$
\begin{align*}
& c_{0}(\lambda, x)=\cos (\sqrt{\lambda}(x-a))+O\left(\frac{1}{\sqrt{\lambda}}\right) \\
& s_{0}(\lambda, x)=\frac{1}{\sqrt{\lambda}} \sin (\sqrt{\lambda}(x-a))+O\left(\frac{1}{\lambda}\right), \tag{9.77}
\end{align*}
$$

as $\lambda \rightarrow \infty$.
From this lemma we obtain
Lemma 9.19. The Weyl m-function satisfies

$$
m_{b}(z)= \begin{cases}-\cot (\alpha)+O\left(\frac{1}{\sqrt{-z}}\right), & \alpha \neq 0  \tag{9.78}\\ -\sqrt{-z}+O(1), & \alpha=0,\end{cases}
$$

as $z \rightarrow \infty$ in any sector $|\operatorname{Re}(z)| \leq C|\operatorname{Im}(z)|$.
Proof. As in the proof of Theorem 9.17 we obtain from Lemma 9.15

$$
G(z, x, x)=d(x)+\int_{\mathbb{R}}\left(\frac{1}{\lambda-z}-\frac{\lambda}{1+\lambda^{2}}\right) s(\lambda, x)^{2} d \mu(\lambda) .
$$

Hence, since the integrand converges pointwise to 0 , dominated convergence (Problem 9.13) implies $G(z, x, x)=o(z)$ as $z \rightarrow \infty$ in any sector $|\operatorname{Re}(z)| \leq$ $C|\operatorname{Im}(z)|$. Now solving $G(z, x, y)=s(z, x) u_{b}(z, x)$ for $m_{b}(z)$ and using the asymptotic expansions from Lemma 9.18, we see

$$
m_{b}(z)=-\frac{c(z, x)}{s(z, x)}+o\left(z \mathrm{e}^{-2 \sqrt{-z}(x-a)}\right)
$$

from which the claim follows.
Note that assuming $q \in C^{k}([a, b))$, one can obtain further asymptotic terms in Lemma 9.18 and hence also in the expansion of $m_{b}(z)$.

The asymptotics of $m_{b}(z)$ in turn tell us more about $L^{2}(\mathbb{R}, d \mu)$.

Lemma 9.20. Let

$$
F(z)=d+\int_{\mathbb{R}}\left(\frac{1}{\lambda-z}-\frac{\lambda}{1+\lambda^{2}}\right) d \mu(\lambda)
$$

be a Herglotz function. Then, for any $0<\gamma<2$, we have

$$
\begin{equation*}
\int_{\mathbb{R}} \frac{d \mu(\lambda)}{1+|\lambda|^{\gamma}}<\infty \quad \Longleftrightarrow \quad \int_{1}^{\infty} \frac{\operatorname{Im}(F(\mathrm{i} y))}{y^{\gamma}} d y<\infty . \tag{9.79}
\end{equation*}
$$

Proof. First of all note that we can split $F(z)=F_{1}(z)+F_{2}(z)$ according to $d \mu=\chi_{[-1,1]} d \mu+\left(1+\chi_{[-1,1]}\right) d \mu$. The part $F_{1}(z)$ corresponds to a finite measure and does not contribute by Theorem 3.20. Hence we can assume that $\mu$ is not supported near 0 . Then Fubini shows

$$
\int_{0}^{\infty} \frac{\operatorname{Im}(F(\mathrm{i} y))}{y^{\gamma}} d y=\int_{0}^{\infty} \int_{\mathbb{R}} \frac{y^{1-\gamma}}{\lambda^{2}+y^{2}} d \mu(\lambda) d y=\frac{\pi / 2}{\sin (\gamma \pi / 2)} \int_{\mathbb{R}} \frac{1}{|\lambda|^{\gamma}} d \mu(\lambda),
$$

which proves the claim. Here we have used (Problem 9.14)

$$
\int_{0}^{\infty} \frac{y^{1-\gamma}}{\lambda^{2}+y^{2}} d y=\frac{\pi / 2}{|\lambda|^{\gamma} \sin (\gamma \pi / 2)}
$$

For the case $\gamma=0$ see Theorem 3.20 and for the case $\gamma=2$ see Problem 9.15.

Corollary 9.21. We have

$$
\begin{equation*}
G(z, x, y)=\int_{\mathbb{R}} \frac{s(\lambda, x) s(\lambda, y)}{\lambda-z} d \mu(\lambda) \tag{9.80}
\end{equation*}
$$

where the integrand is integrable. Moreover, for any $\varepsilon>0$ we have

$$
\begin{equation*}
G(z, x, y)=O\left(z^{-1 / 2+\varepsilon} \mathrm{e}^{-\sqrt{-z}|y-x|}\right), \tag{9.81}
\end{equation*}
$$

as $z \rightarrow \infty$ in any sector $|\operatorname{Re}(z)| \leq C|\operatorname{Im}(z)|$.
Proof. The previous lemma implies $\int s(\lambda, x)^{2}(1+|\lambda|)^{\gamma} d \mu(\lambda)<\infty$ for $\gamma>\frac{1}{2}$. This already proves the first part and also the second in the case $x=y$, and hence the result follows from $|\lambda-z|^{-1} \leq$ const $\operatorname{Im}(z)^{-1 / 2+\varepsilon}\left(1+\lambda^{2}\right)^{-1 / 4-\varepsilon / 2}$ (Problem 9.13) in any sector $|\operatorname{Re}(z)| \leq C|\operatorname{Im}(z)|$. But the case $x=y$ implies

$$
u_{b}(z, x)=O\left(z^{-1 / 2+\varepsilon} \mathrm{e}^{-\sqrt{-z}(a-x)}\right),
$$

which in turn implies the $x \neq y$ case.
Now we come to our main result of this section:

Theorem 9.22. Suppose $\tau_{j}, j=0,1$, are given on $(a, b)$ and both are regular at a. Moreover, $A_{j}$ are some self-adjoint operators associated with $\tau_{j}$ and the same boundary condition at $a$.

Let $c \in(0, b)$. Then $q_{0}(x)=q_{1}(x)$ for $x \in(a, c)$ if and only if for every $\varepsilon>0$ we have that $m_{1, b}(z)-m_{0, b}(z)=O\left(\mathrm{e}^{-2(a-\varepsilon) \operatorname{Re}(\sqrt{-z})}\right)$ as $z \rightarrow \infty$ along some nonreal ray.

Proof. By (9.75) we have $s_{1}(z, x) / s_{0}(z, x) \rightarrow 1$ as $z \rightarrow \infty$ along any nonreal ray. Moreover, (9.81) in the case $y=x$ shows $s_{0}(z, x) u_{1, b}(z, x) \rightarrow 0$ and $s_{1}(z, x) u_{0, b}(z, x) \rightarrow 0$ as well. In particular, the same is true for the difference

$$
s_{1}(z, x) c_{0}(z, x)-s_{0}(z, x) c_{1}(z, x)+\left(m_{1, b}(z)-m_{0, b}(z)\right) s_{0}(z, x) s_{1}(z, x) .
$$

Since the first two terms cancel for $x \in(a, c)$, (9.75) implies $m_{1, b}(z)-$ $m_{0, b}(z)=O\left(\mathrm{e}^{-2(a-\varepsilon) \operatorname{Re}(\sqrt{-z})}\right)$.

To see the converse, first note that the entire function

$$
\begin{aligned}
s_{1}(z, x) c_{0}(z, x)-s_{0}(z, x) c_{1}(z, x)= & s_{1}(z, x) u_{0, b}(z, x)-s_{0}(z, x) u_{1, b}(z, x) \\
& -\left(m_{1, b}(z)-m_{0, b}(z)\right) s_{0}(z, x) s_{1}(z, x)
\end{aligned}
$$

vanishes as $z \rightarrow \infty$ along any nonreal ray for fixed $x \in(a, c)$ by the same arguments used before together with the assumption on $m_{1, b}(z)-m_{0, b}(z)$. Moreover, by (9.75) this function has an order of growth $\leq 1 / 2$ and thus by the Phragmén-Lindelöf theorem (e.g., [53, Thm. 4.3.4]) is bounded on all of $\mathbb{C}$. By Liouville's theorem it must be constant and since it vanishes along rays, it must be zero; that is, $s_{1}(z, x) c_{0}(z, x)=s_{0}(z, x) c_{1}(z, x)$ for all $z \in \mathbb{C}$ and $x \in(a, c)$. Differentiating this identity with respect to $x$ and using $W\left(c_{j}(z), s_{j}(z)\right)=1$ shows $s_{1}(z, x)^{2}=s_{0}(z, x)^{2}$. Taking the logarithmic derivative further gives $s_{1}^{\prime}(z, x) / s_{1}(z, x)=s_{0}^{\prime}(z, x) / s_{0}(z, x)$ and differentiating once more shows $s_{1}^{\prime \prime}(z, x) / s_{1}(z, x)=s_{0}^{\prime \prime}(z, x) / s_{0}(z, x)$. This finishes the proof since $q_{j}(x)=z+s_{j}^{\prime \prime}(z, x) / s_{j}(z, x)$.

Problem 9.12. Prove Lemma 9.18. (Hint: Without loss set $a=0$. Now use that

$$
\begin{aligned}
c(z, x)= & \cos (\alpha) \cosh (\sqrt{-z} x)-\frac{\sin (\alpha)}{\sqrt{-z}} \sinh (\sqrt{-z} x) \\
& -\frac{1}{\sqrt{-z}} \int_{0}^{x} \sinh (\sqrt{-z}(x-y)) q(y) c(z, y) d y
\end{aligned}
$$

by Lemma 9.2 and consider $\tilde{c}(z, x)=\mathrm{e}^{-\sqrt{-z} x} c(z, x)$.)
Problem 9.13. Show

$$
\begin{equation*}
\left|\frac{1}{\lambda-z}\right| \leq \frac{2}{\sqrt{1+\lambda^{2}}} \frac{|z|}{\operatorname{Im}(z)} \tag{9.82}
\end{equation*}
$$

and

$$
\begin{equation*}
\left|\frac{1}{\lambda-z}-\frac{\lambda}{1+\lambda^{2}}\right| \leq \frac{2}{1+\lambda^{2}} \frac{(1+|z|)|z|}{\operatorname{Im}(z)} \tag{9.83}
\end{equation*}
$$

for any $\lambda \in \mathbb{R}$. (Hint: To obtain the first, search for the maximum as a function of $\lambda$ (cf. also Problem 3.7). The second then follows from the first.)

Problem 9.14. Show

$$
\int_{0}^{\infty} \frac{y^{1-\gamma}}{1+y^{2}} d y=\frac{\pi / 2}{\sin (\gamma \pi / 2)}, \quad \gamma \in(0,2)
$$

by proving

$$
\int_{-\infty}^{\infty} \frac{\mathrm{e}^{\alpha x}}{1+\mathrm{e}^{x}} d x=\frac{\pi}{\sin (\gamma \pi)}, \quad \alpha \in(0,1)
$$

(Hint: To compute the last integral, use a contour consisting of the straight lines connecting the points $-R, R, R+2 \pi \mathrm{i},-R+2 \pi \mathrm{i}$. Evaluate the contour integral using the residue theorem and let $R \rightarrow \infty$. Show that the contributions from the vertical lines vanish in the limit and relate the integrals along the horizontal lines.)

Problem 9.15. In Lemma 9.20 we assumed $0<\gamma<2$. Show that in the case $\gamma=2$ we have

$$
\int_{\mathbb{R}} \frac{\log \left(1+\lambda^{2}\right)}{1+\lambda^{2}} d \mu(\lambda)<\infty \quad \Longleftrightarrow \quad \int_{1}^{\infty} \frac{\operatorname{Im}(F(\mathrm{i} y))}{y^{2}} d y<\infty
$$

(Hint: $\int_{1}^{\infty} \frac{y^{-1}}{\lambda^{2}+y^{2}} d y=\frac{\log \left(1+\lambda^{2}\right)}{2 \lambda^{2}}$.)

### 9.5. Absolutely continuous spectrum

In this section we will show how to locate the absolutely continuous spectrum. We will again assume that $a$ is a regular endpoint. Moreover, we assume that $b$ is $l . p$. since otherwise the spectrum is discrete and there will be no absolutely continuous spectrum.

In this case we have seen in the Section 9.3 that $A$ is unitarily equivalent to multiplication by $\lambda$ in the space $L^{2}(\mathbb{R}, d \mu)$, where $\mu$ is the measure associated to the Weyl m-function. Hence by Theorem 3.23 we conclude that the set

$$
\begin{equation*}
M_{s}=\left\{\lambda \mid \underset{\varepsilon \downarrow 0}{\lim \sup } \operatorname{Im}\left(m_{b}(\lambda+\mathrm{i} \varepsilon)\right)=\infty\right\} \tag{9.84}
\end{equation*}
$$

is a support for the singularly continuous part and

$$
\begin{equation*}
M_{a c}=\left\{\lambda \mid 0<\underset{\varepsilon \downarrow 0}{\lim \sup } \operatorname{Im}\left(m_{b}(\lambda+\mathrm{i} \varepsilon)\right)<\infty\right\} \tag{9.85}
\end{equation*}
$$

is a minimal support for the absolutely continuous part. Moreover, $\sigma\left(A_{a c}\right)$ can be recovered from the essential closure of $M_{a c}$; that is,

$$
\begin{equation*}
\sigma\left(A_{a c}\right)=\bar{M}_{a c}^{e s s} . \tag{9.86}
\end{equation*}
$$

Compare also Section 3.2.
We now begin our investigation with a crucial estimate on $\operatorname{Im}\left(m_{b}(\lambda+\mathrm{i} \varepsilon)\right)$. Set

$$
\begin{equation*}
\|f\|_{(a, x)}=\sqrt{\int_{a}^{x}|f(y)|^{2} r(y) d y}, \quad x \in(a, b) . \tag{9.87}
\end{equation*}
$$

Lemma 9.23. Let

$$
\begin{equation*}
\varepsilon=\left(2\|s(\lambda)\|_{(1, x)}\|c(\lambda)\|_{(a, x)}\right)^{-1} \tag{9.88}
\end{equation*}
$$

and note that since $b$ is l.p., there is a one-to-one correspondence between $\varepsilon \in(0, \infty)$ and $x \in(a, b)$. Then

$$
\begin{equation*}
5-\sqrt{24} \leq\left|m_{b}(\lambda+\mathrm{i} \varepsilon)\right| \frac{\|s(\lambda)\|_{(a, x)}}{\|c(\lambda)\|_{(a, x)}} \leq 5+\sqrt{24} . \tag{9.89}
\end{equation*}
$$

Proof. Let $x>a$. Then by Lemma 9.2

$$
\begin{aligned}
& u_{+}(\lambda+\mathrm{i} \varepsilon, x)=c(\lambda, x)-m_{b}(\lambda+\mathrm{i} \varepsilon) s(\lambda, x) \\
& \quad-\mathrm{i} \varepsilon \int_{a}^{x}(c(\lambda, x) s(\lambda, y)-c(\lambda, y) s(\lambda, x)) u_{+}(\lambda+\mathrm{i} \varepsilon, y) r(y) d y .
\end{aligned}
$$

Hence one obtains after a little calculation (as in the proof of Theorem 9.9)

$$
\begin{aligned}
\left\|c(\lambda)-m_{b}(\lambda+\mathrm{i} \varepsilon) s(\lambda)\right\|_{(a, x)} \leq & \left\|u_{b}(\lambda+\mathrm{i} \varepsilon)\right\|_{(a, x)} \\
& +2 \varepsilon\|s(\lambda)\|_{(a, x)}\|c(\lambda)\|_{(a, x)}\left\|u_{b}(\lambda+\mathrm{i} \varepsilon)\right\|_{(a, x)} .
\end{aligned}
$$

Using the definition of $\varepsilon$ and (9.55), we obtain

$$
\begin{aligned}
\left\|c(\lambda)-m_{b}(\lambda+\mathrm{i} \varepsilon) s(\lambda)\right\|_{(a, x)}^{2} & \leq 4\left\|u_{b}(\lambda+\mathrm{i} \varepsilon)\right\|_{(a, x)}^{2} \\
& \leq 4\left\|u_{b}(\lambda+\mathrm{i} \varepsilon)\right\|_{(a, b)}^{2}=\frac{4}{\varepsilon} \operatorname{Im}\left(m_{b}(\lambda+\mathrm{i} \varepsilon)\right) \\
& \leq 8\|s(\lambda)\|_{(a, x)}\|c(\lambda)\|_{(a, x)} \operatorname{Im}\left(m_{b}(\lambda+\mathrm{i} \varepsilon)\right) .
\end{aligned}
$$

Combining this estimate with

$$
\left\|c(\lambda)-m_{b}(\lambda+\mathrm{i} \varepsilon) s(\lambda)\right\|_{(a, x)}^{2} \geq\left(\|c(\lambda)\|_{(a, x)}-\left|m_{b}(\lambda+\mathrm{i} \varepsilon)\right|\|s(\lambda)\|_{(a, x)}\right)^{2}
$$

shows $(1-t)^{2} \leq 8 t$, where $t=\left|m_{b}(\lambda+\mathrm{i} \varepsilon)\right|\|s(\lambda)\|_{(a, x)}\|c(\lambda)\|_{(a, x)}^{-1}$.
We now introduce the concept of subordinacy. A nonzero solution $u$ of $\tau u=z u$ is called sequentially subordinate at $b$ with respect to another solution $v$ if

$$
\begin{equation*}
\liminf _{x \rightarrow b} \frac{\|u\|_{(a, x)}}{\|v\|_{(a, x)}}=0 . \tag{9.90}
\end{equation*}
$$

If the liminf can be replaced by a lim, the solution is called subordinate. Both concepts will eventually lead to the same results (cf. Remark 9.26 below). We will work with (9.90) since this will simplify proofs later on and hence we will drop the additional sequentially.

It is easy to see that if $u$ is subordinate with respect to $v$, then it is subordinate with respect to any linearly independent solution. In particular, a subordinate solution is unique up to a constant. Moreover, if a solution $u$ of $\tau u=\lambda u, \lambda \in \mathbb{R}$, is subordinate, then it is real up to a constant, since both the real and the imaginary parts are subordinate. For $z \in \mathbb{C} \backslash \mathbb{R}$ we know that there is always a subordinate solution near $b$, namely $u_{b}(z, x)$. The following result considers the case $z \in \mathbb{R}$.

Lemma 9.24. Let $\lambda \in \mathbb{R}$. There is a subordinate solution $u(\lambda)$ near $b$ if and only if there is a sequence $\varepsilon_{n} \downarrow 0$ such that $m_{b}\left(\lambda+\mathrm{i} \varepsilon_{n}\right)$ converges to $a$ limit in $\mathbb{R} \cup\{\infty\}$ as $n \rightarrow \infty$. Moreover,

$$
\begin{equation*}
\lim _{n \rightarrow \infty} m_{b}\left(\lambda+\mathrm{i} \varepsilon_{n}\right)=\frac{\cos (\alpha) p(a) u^{\prime}(\lambda, a)+\sin (\alpha) u(\lambda, a)}{\cos (\alpha) u(\lambda, a)-\sin (\alpha) p(a) u^{\prime}(\lambda, a)} \tag{9.91}
\end{equation*}
$$

in this case (compare (9.52)).
Proof. We will consider the number $\alpha$ fixing the boundary condition as a parameter and write $s_{\alpha}(z, x), c_{\alpha}(z, x), m_{b, \alpha}$, etc., to emphasize the dependence on $\alpha$.

Every solution can (up to a constant) be written as $s_{\beta}(\lambda, x)$ for some $\beta \in[0, \pi)$. But by Lemma $9.23, s_{\beta}(\lambda, x)$ is subordinate if and only there is a sequence $\varepsilon_{n} \downarrow 0$ such that $\lim _{n \rightarrow \infty} m_{b, \beta}\left(\lambda+\mathrm{i} \varepsilon_{n}\right)=\infty$ and by (9.71) this is the case if and only if
$\lim _{n \rightarrow \infty} m_{b, \alpha}\left(\lambda+\mathrm{i} \varepsilon_{n}\right)=\lim _{n \rightarrow \infty} \frac{\cos (\alpha-\beta) m_{b, \beta}\left(\lambda+\mathrm{i} \varepsilon_{n}\right)+\sin (\alpha-\beta)}{\cos (\alpha-\beta)-\sin (\alpha-\beta) m_{b, \beta}\left(\lambda+\mathrm{i} \varepsilon_{n}\right)}=\cot (\alpha-\beta)$ is a number in $\mathbb{R} \cup\{\infty\}$.

We are interested in $N(\tau)$, the set of all $\lambda \in \mathbb{R}$ for which no subordinate solution exists, that is,

$$
\begin{equation*}
N(\tau)=\{\lambda \in \mathbb{R} \mid \text { No solution of } \tau u=\lambda u \text { is subordinate at } b\} \tag{9.92}
\end{equation*}
$$

and the set

$$
\begin{equation*}
S_{\alpha}(\tau)=\{\lambda \mid s(\lambda, x) \text { is subordinate at } b\} . \tag{9.93}
\end{equation*}
$$

From the previous lemma we obtain
Corollary 9.25. We have $\lambda \in N(\tau)$ if and only if

$$
\liminf _{\varepsilon \downarrow 0} \operatorname{Im}\left(m_{b}(\lambda+\mathrm{i} \varepsilon)\right)>0 \quad \text { and } \quad \underset{\varepsilon \downarrow 0}{\limsup }\left|m_{b}(\lambda+\mathrm{i} \varepsilon)\right|<\infty .
$$

Similarly, $\lambda \in S_{\alpha}(\tau)$ if and only if $\lim \sup _{\varepsilon \downarrow 0}\left|m_{b}(\lambda+\mathrm{i} \varepsilon)\right|=\infty$.

Remark 9.26. Since the set, for which the limit $\lim _{\varepsilon \downarrow 0} m_{b}(\lambda+\mathrm{i} \varepsilon)$ does not exist, is of zero spectral and Lebesgue measure (Corollary 3.25), changing the $\lim$ in (9.90) to a liminf will affect $N(\tau)$ only on such a set (which is irrelevant for our purpose). Moreover, by (9.71) the set where the limit exists (finitely or infinitely) is independent of the boundary condition $\alpha$.

Then, as a consequence of the previous corollary, we have
Theorem 9.27. The set $N(\tau) \subseteq M_{a c}$ is a minimal support for the absolutely continuous spectrum of $H$. In particular,

$$
\begin{equation*}
\sigma_{a c}(H)=\overline{N(\tau)}^{e s s} . \tag{9.94}
\end{equation*}
$$

Moreover, the set $S_{\alpha}(\tau) \supseteq M_{s}$ is a minimal support for the singular spectrum of $H$.

Proof. By our corollary we have $N(\tau) \subseteq M_{a c}$. Moreover, if $\lambda \in M_{a c} \backslash N(\tau)$, then either $0=\lim \inf \operatorname{Im}\left(m_{b}\right)<\lim \sup \operatorname{Im}\left(m_{b}\right)$ or $\lim \sup \operatorname{Re}\left(m_{b}\right)=\infty$. The first case can only happen on a set of Lebesgue measure zero by Theorem 3.23 and the same is true for the second by Corollary 3.25 .

Similarly, by our corollary we also have $S_{\alpha}(\tau) \supseteq M_{s}$ and $\lambda \in S_{\alpha}(\tau) \backslash M_{s}$ happens precisely when $\lim \sup \operatorname{Re}\left(m_{b}\right)=\infty$ which can only happen on a set of Lebesgue measure zero by Corollary 3.25.

Note that if $\left(\lambda_{1}, \lambda_{2}\right) \subseteq N(\tau)$, then the spectrum of any self-adjoint extension $H$ of $\tau$ is purely absolutely continuous in the interval $\left(\lambda_{1}, \lambda_{2}\right)$.
Example. Consider $H_{0}=-\frac{d^{2}}{d x^{2}}$ on $(0, \infty)$ with a Dirichlet boundary condition at $x=0$. Then it is easy to check $H_{0} \geq 0$ and $N\left(\tau_{0}\right)=(0, \infty)$. Hence $\sigma_{a c}\left(H_{0}\right)=[0, \infty)$. Moreover, since the singular spectrum is supported on $[0, \infty) \backslash N\left(\tau_{0}\right)=\{0\}$, we see $\sigma_{s c}\left(H_{0}\right)=\emptyset$ (since the singular continuous spectrum cannot be supported on a finite set) and $\sigma_{p p}\left(H_{0}\right) \subseteq\{0\}$. Since 0 is no eigenvalue, we have $\sigma_{p p}\left(H_{0}\right)=\emptyset$.

Problem 9.16. Determine the spectrum of $H_{0}=-\frac{d^{2}}{d x^{2}}$ on $(0, \infty)$ with a general boundary condition (9.44) at $a=0$.

### 9.6. Spectral transformations II

In Section 9.3 we have looked at the case of one regular endpoint. In this section we want to remove this restriction. In the case of a regular endpoint (or more generally an l.c. endpoint), the choice of $u(\lambda, x)$ in Lemma 9.13 was dictated by the fact that $u(\lambda, x)$ is required to satisfy the boundary condition at the regular (l.c.) endpoint. We begin by showing that in the general case we can choose any pair of linearly independent solutions. We will choose
some arbitrary point $c \in I$ and two linearly independent solutions according to the initial conditions

$$
\begin{equation*}
c(z, c)=1, \quad p(c) c^{\prime}(z, c)=0, \quad s(z, c)=0, \quad p(c) s^{\prime}(z, c)=1 . \tag{9.95}
\end{equation*}
$$

We will abbreviate

$$
\begin{equation*}
\underline{s}(z, x)=\binom{c(z, x)}{s(z, x)} . \tag{9.96}
\end{equation*}
$$

Lemma 9.28. There is measure $d \mu(\lambda)$ and a nonnegative matrix $R(\lambda)$ with trace one such that

$$
\begin{align*}
& U: L^{2}(I, r d x) \rightarrow L^{2}(\mathbb{R}, R d \mu) \\
& f(x) \quad \mapsto \int_{a}^{b} \underline{s}(\lambda, x) f(x) r(x) d x \tag{9.97}
\end{align*}
$$

is a spectral mapping as in Lemma 9.13. As before, the integral has to be understood as $\int_{a}^{b} d x=\lim _{c \downarrow a, d \uparrow b} \int_{c}^{d} d x$ with limit taken in $L^{2}(\mathbb{R}, R d \mu)$, where $L^{2}(\mathbb{R}, R d \mu)$ is the Hilbert space of all $\mathbb{C}^{2}$-valued measurable functions with scalar product

$$
\begin{equation*}
\langle\underline{f}, \underline{g}\rangle=\int_{\mathbb{R}} \underline{f}^{*} R \underline{g} d \mu . \tag{9.98}
\end{equation*}
$$

The inverse is given by

$$
\begin{equation*}
\left(U^{-1} \underline{F}\right)(x)=\int_{\mathbb{R}} \underline{s}(\lambda, x) R(\lambda) \underline{F}(\lambda) d \mu(\lambda) . \tag{9.99}
\end{equation*}
$$

Proof. Let $U_{0}$ be a spectral transformation as in Lemma 9.13 with corresponding real solutions $u_{j}(\lambda, x)$ and measures $d \mu_{j}(x), 1 \leq j \leq k$. Without loss of generality we can assume $k=2$ since we can always choose $d \mu_{2}=0$ and $u_{2}(\lambda, x)$ such that $u_{1}$ and $u_{2}$ are linearly independent.

Now define the $2 \times 2$ matrix $C(\lambda)$ via

$$
\binom{u_{1}(\lambda, x)}{u_{2}(\lambda, x)}=C(\lambda)\binom{c(\lambda, x)}{s(\lambda, x)}
$$

and note that $C(\lambda)$ is nonsingular since $u_{1}, u_{2}$ as well as $s, c$ are linearly independent.

Set $d \tilde{\mu}=d \mu_{1}+d \mu_{2}$. Then $d \mu_{j}=r_{j} d \tilde{\mu}$ and we can introduce $\tilde{R}=$ $C^{*}\left(\begin{array}{cc}r_{1} & 0 \\ 0 & r_{2}\end{array}\right) C$. By construction $\tilde{R}$ is a (symmetric) nonnegative matrix. Moreover, since $C(\lambda)$ is nonsingular, $\operatorname{tr}(\tilde{R})$ is positive a.e. with respect to $\tilde{\mu}$. Thus we can set $R=\operatorname{tr}(\tilde{R})^{-1} \tilde{R}$ and $d \mu=\operatorname{tr}(\tilde{R})^{-1} d \tilde{\mu}$.

This matrix gives rise to an operator

$$
C: L^{2}(\mathbb{R}, R d \mu) \rightarrow \bigoplus_{j} L^{2}\left(\mathbb{R}, d \mu_{j}\right), \quad F(\lambda) \mapsto C(\lambda) F(\lambda)
$$

which, by our choice of $R d \mu$, is norm preserving. By $C U=U_{0}$ it is onto and hence it is unitary (this also shows that $L^{2}(\mathbb{R}, R d \mu)$ is a Hilbert space, i.e., complete).

It is left as an exercise to check that $C$ maps multiplication by $\lambda$ in $L^{2}(\mathbb{R}, R d \mu)$ to multiplication by $\lambda$ in $\bigoplus_{j} L^{2}\left(\mathbb{R}, d \mu_{j}\right)$ and the formula for $U^{-1}$.

Clearly the matrix-valued measure $R d \mu$ contains all the spectral information of $A$. Hence it remains to relate it to the resolvent of $A$ as in Section 9.3

For our base point $x=c$ there are corresponding Weyl $m$-functions $m_{a}(z)$ and $m_{b}(z)$ such that

$$
\begin{equation*}
u_{a}(z)=c(z, x)-m_{a}(z) s(z, x), \quad u_{b}(z)=c(z, x)+m_{b}(z) s(z, x) . \tag{9.100}
\end{equation*}
$$

The different sign in front of $m_{a}(z)$ is introduced such that $m_{a}(z)$ will again be a Herglotz function. In fact, this follows using reflection at $c, x-c \mapsto$ $-(x-c)$, which will interchange the roles of $m_{a}(z)$ and $m_{b}(z)$. In particular, all considerations from Section 9.3 hold for $m_{a}(z)$ as well.

Furthermore, we will introduce the Weyl $M$-matrix

$$
M(z)=\frac{1}{m_{a}(z)+m_{b}(z)}\left(\begin{array}{cc}
-1 & \left(m_{a}(z)-m_{b}(z)\right) / 2  \tag{9.101}\\
\left(m_{a}(z)-m_{b}(z)\right) / 2 & m_{a}(z) m_{b}(z)
\end{array}\right) .
$$

Note $\operatorname{det}(M(z))=-\frac{1}{4}$. Since

$$
\begin{equation*}
m_{a}(z)=-\frac{p(c) u_{a}^{\prime}(z, c)}{u_{a}(z, c)} \quad \text { and } \quad m_{b}(z)=\frac{p(c) u_{b}^{\prime}(z, c)}{u_{b}(z, c)} \tag{9.102}
\end{equation*}
$$

it follows that $W\left(u_{a}(z), u_{b}(z)\right)=m_{a}(z)+m_{b}(z)$ and

$$
\begin{align*}
& M(z)= \\
& \lim _{x, y \rightarrow c}\left(\begin{array}{cc}
G(z, x, x) & \left(p(x) \partial_{x}+p(y) \partial_{y}\right) G(z, x, y) / 2 \\
\left(p(x) \partial_{x}+p(y) \partial_{y}\right) G(z, x, y) / 2 & p(x) \partial_{x} p(y) \partial_{y} G(z, x, y)
\end{array}\right), \tag{9.103}
\end{align*}
$$

where $G(z, x, y)$ is the Green function of $A$. The limit is necessary since $\partial_{x} G(z, x, y)$ has different limits as $y \rightarrow x$ from $y>x$, respectively, $y<x$.

We begin by showing
Lemma 9.29. Let $U$ be the spectral mapping from the previous lemma. Then

$$
\begin{align*}
(U G(z, x, .))(\lambda) & =\frac{1}{\lambda-z} \underline{s}(\lambda, x), \\
\left(U p(x) \partial_{x} G(z, x, .)\right)(\lambda) & =\frac{1}{\lambda-z} p(x) \underline{s}^{\prime}(\lambda, x) \tag{9.104}
\end{align*}
$$

for every $x \in(a, b)$ and every $z \in \rho(A)$.

Proof. First of all note that $G(z, x,.) \in L^{2}((a, b), r d x)$ for every $x \in(a, b)$ and $z \in \rho(A)$. Moreover, from $R_{A}(z) f=U^{-1} \frac{1}{\lambda-z} U f$ we have

$$
\int_{a}^{b} G(z, x, y) f(y) r(y) d y=\int_{\mathbb{R}} \frac{1}{\lambda-z} \underline{s}(\lambda, x) R(\lambda) \underline{F}(\lambda) d \mu(\lambda)
$$

where $\underline{F}=U f$. Now proceed as in the proof of Lemma 9.15.
With the aid of this lemma we can now show
Theorem 9.30. The Weyl $M$-matrix is given by

$$
\begin{equation*}
M(z)=D+\int_{\mathbb{R}}\left(\frac{1}{\lambda-z}-\frac{\lambda}{1+\lambda^{2}}\right) R(\lambda) d \mu(\lambda), \quad D_{j k} \in \mathbb{R}, \tag{9.105}
\end{equation*}
$$

and

$$
\begin{equation*}
D=\operatorname{Re}(M(\mathrm{i})), \quad \int_{\mathbb{R}} \frac{1}{1+\lambda^{2}} R(\lambda) d \mu(\lambda)=\operatorname{Im}(M(\mathrm{i})) \tag{9.106}
\end{equation*}
$$

where

$$
\begin{equation*}
\operatorname{Re}(M(z))=\frac{1}{2}\left(M(z)+M^{*}(z)\right), \quad \operatorname{Im}(M(z))=\frac{1}{2}\left(M(z)-M^{*}(z)\right) . \tag{9.107}
\end{equation*}
$$

Proof. By the previous lemma we have

$$
\int_{a}^{b}|G(z, c, y)|^{2} r(y) d y=\int_{\mathbb{R}} \frac{1}{|z-\lambda|^{2}} R_{11}(\lambda) d \mu(\lambda)
$$

Moreover by (9.28), (9.55), and (9.100) we infer

$$
\begin{aligned}
\int_{a}^{b}|G(z, c, y)|^{2} r(y) d y= & \frac{1}{\left|W\left(u_{a}, u_{b}\right)\right|^{2}}\left(\left|u_{b}(z, c)\right|^{2} \int_{a}^{c}\left|u_{a}(z, y)\right|^{2} r(y) d y\right. \\
& \left.+\left|u_{a}(z, c)\right|^{2} \int_{c}^{b}\left|u_{b}(z, y)\right|^{2} r(y) d y\right)=\frac{\operatorname{Im}\left(M_{11}(z)\right)}{\operatorname{Im}(z)} .
\end{aligned}
$$

Similarly we obtain

$$
\int_{\mathbb{R}} \frac{1}{|z-\lambda|^{2}} R_{22}(\lambda) d \mu(\lambda)=\frac{\operatorname{Im}\left(M_{22}(z)\right)}{\operatorname{Im}(z)}
$$

and

$$
\int_{\mathbb{R}} \frac{1}{|z-\lambda|^{2}} R_{12}(\lambda) d \mu(\lambda)=\frac{\operatorname{Im}\left(M_{12}(z)\right)}{\operatorname{Im}(z)}
$$

Hence the result follows as in the proof of Theorem 9.17.
Now we are also able to extend Theorem 9.27. Note that by

$$
\begin{equation*}
\operatorname{tr}(M(z))=M_{11}(z)+M_{22}(z)=d+\int_{\mathbb{R}}\left(\frac{1}{\lambda-z}-\frac{\lambda}{1+\lambda^{2}}\right) d \mu(\lambda) \tag{9.108}
\end{equation*}
$$

(with $d=\operatorname{tr}(D) \in \mathbb{R}$ ) we have that the set

$$
\begin{equation*}
M_{s}=\{\lambda \mid \underset{\varepsilon \downarrow 0}{\lim \sup } \operatorname{Im}(\operatorname{tr}(M(\lambda+\mathrm{i} \varepsilon)))=\infty\} \tag{9.109}
\end{equation*}
$$

is a support for the singularly continuous part and

$$
\begin{equation*}
M_{a c}=\{\lambda \mid 0<\underset{\varepsilon \downarrow 0}{\lim \sup } \operatorname{Im}(\operatorname{tr}(M(\lambda+\mathrm{i} \varepsilon)))<\infty\} \tag{9.110}
\end{equation*}
$$

is a minimal support for the absolutely continuous part.
Theorem 9.31. The set $N_{a}(\tau) \cup N_{b}(\tau) \subseteq M_{a c}$ is a minimal support for the absolutely continuous spectrum of $H$. In particular,

$$
\begin{equation*}
\sigma_{a c}(H)={\overline{N_{a}(\tau) \cup N_{b}(\tau)}}^{e s s} \tag{9.111}
\end{equation*}
$$

Moreover, the set

$$
\begin{equation*}
\bigcup_{\alpha \in[0, \pi)} S_{a, \alpha}(\tau) \cap S_{b, \alpha}(\tau) \supseteq M_{s} \tag{9.112}
\end{equation*}
$$

is a support for the singular spectrum of $H$.
Proof. By Corollary 9.25 we have $0<\lim \inf \operatorname{Im}\left(m_{a}\right)$ and $\lim \sup \left|m_{a}\right|<\infty$ if and only if $\lambda \in N_{a}(\tau)$ and similarly for $m_{b}$.

Now suppose $\lambda \in N_{a}(\tau)$. Then limsup $\left|M_{11}\right|<\infty$ since limsup $\left|M_{11}\right|=$ $\infty$ is impossible by $0=\liminf \left|M_{11}^{-1}\right|=\liminf \left|m_{a}+m_{b}\right| \geq \liminf \operatorname{Im}\left(m_{a}\right)>$ 0 . Similarly limsup $\left|M_{22}\right|<\infty$. Moreover, if $\lim \sup \left|m_{b}\right|<\infty$, we also have $\liminf \operatorname{Im}\left(M_{11}\right)=\liminf \frac{\operatorname{Im}\left(m_{a}+m_{b}\right)}{\left|m_{a}+m_{b}\right|^{2}} \geq \frac{\liminf \operatorname{Im}\left(m_{a}\right)}{\limsup \left|m_{a}\right|^{2}+\limsup \left|m_{b}\right|^{2}}>0$ and if $\lim \sup \left|m_{b}\right|=\infty$, we have

$$
\lim \inf \operatorname{Im}\left(M_{22}\right)=\lim \inf \operatorname{Im}\left(\frac{m_{a}}{1+\frac{m_{a}}{m_{b}}}\right) \geq \lim \inf \operatorname{Im}\left(m_{a}\right)>0
$$

Thus $N_{a}(\tau) \subseteq M_{a c}$ and similarly $N_{b}(\tau) \subseteq M_{a c}$.
Conversely, let $\lambda \in M_{a c}$. By Corollary 3.25 we can assume that the $\operatorname{limits} \lim m_{a}$ and $\lim m_{b}$ both exist and are finite after disregarding a set of Lebesgue measure zero. For such $\lambda, \lim \operatorname{Im}\left(M_{11}\right)$ and $\lim \operatorname{Im}\left(M_{22}\right)$ both exist and are finite. Moreover, either $\lim \operatorname{Im}\left(M_{11}\right)>0$, in which case $\lim \operatorname{Im}\left(m_{a}+\right.$ $\left.m_{b}\right)>0$, or $\lim \operatorname{Im}\left(M_{11}\right)=0$, in which case

$$
0<\lim \operatorname{Im}\left(M_{22}\right)=\lim \frac{\left|m_{a}\right|^{2} \operatorname{Im}\left(m_{b}\right)+\left|m_{b}\right|^{2} \operatorname{Im}\left(m_{a}\right)}{\left|m_{a}\right|^{2}+\left|m_{b}\right|^{2}}=0
$$

yields a contradiction. Thus $\lambda \in N_{a}(\tau) \cup N_{b}(\tau)$ and the first part is proven.
To prove the second part, let $\lambda \in M_{s}$. If $\lim \sup \operatorname{Im}\left(M_{11}\right)=\infty$, we have $\limsup \left|M_{11}\right|=\infty$ and thus $\liminf \left|m_{a}+m_{b}\right|=0$. But this implies that there is some subsequence such that $\lim m_{b}=-\lim m_{a}=\cot (\alpha) \in \mathbb{R} \cup\{\infty\}$. Similarly, if $\lim \sup \operatorname{Im}\left(M_{22}\right)=\infty$, we have liminf $\left|m_{a}^{-1}+m_{b}^{-1}\right|=0$ and there is some subsequence such that $\lim m_{b}^{-1}=-\lim m_{a}^{-1}=\tan (\alpha) \in \mathbb{R} \cup\{\infty\}$. This shows $M_{s} \subseteq \bigcup_{\alpha} S_{a, \alpha}(\tau) \cap S_{b, \alpha}(\tau)$.

Problem 9.17. Show
$R(\lambda) d \mu_{a c}(\lambda)=\left(\begin{array}{cc}\frac{\operatorname{Im}\left(m_{a}(\lambda)+m_{b}(\lambda)\right)}{\left.\left|m_{a}(\lambda)\right|\right|^{2}+\left.m_{b}(\lambda)\right|^{2}} & \frac{\operatorname{Im}\left(m_{a}(\lambda) m_{b}^{*}(\lambda)\right)}{\mid m_{a}\left(\lambda|+| m_{b}(\lambda)\right)^{2}} \\ \frac{\operatorname{Im}\left(m_{a}(\lambda) m_{b}^{*}(\lambda)\right)^{2}}{\left|m_{a}(\lambda)\right|^{2}+\left|m_{b}(\lambda)\right|^{2}} & \frac{\left|m_{a}(\lambda)\right|^{2} \operatorname{Im}\left(m_{b}(\lambda)\right)+\mid m_{b}\left(\lambda| |^{2} \operatorname{Im}\left(m_{a}(\lambda)\right)\right.}{\left|m_{a}(\lambda)\right|^{2}+\left|m_{b}(\lambda)\right|^{2}}\end{array}\right) \frac{d \lambda}{\pi}$,
where $m_{a}(\lambda)=\lim _{\varepsilon \downarrow 0} m_{a}(\lambda+\mathrm{i} \varepsilon)$ and similarly for $m_{b}(\lambda)$.
Moreover, show that the choice of solutions

$$
\binom{u_{b}(\lambda, x)}{u_{a}(\lambda, x)}=V(\lambda)\binom{c(\lambda, x)}{s(\lambda, x)},
$$

where

$$
V(\lambda)=\frac{1}{m_{a}(\lambda)+m_{b}(\lambda)}\left(\begin{array}{cc}
1 & m_{b}(\lambda) \\
1 & -m_{a}(\lambda)
\end{array}\right),
$$

diagonalizes the absolutely continuous part,

$$
V^{-1}(\lambda)^{*} R(\lambda) V(\lambda)^{-1} d \mu_{a c}(\lambda)=\frac{1}{\pi}\left(\begin{array}{cc}
\operatorname{Im}\left(m_{a}(\lambda)\right) & 0 \\
0 & \operatorname{Im}\left(m_{b}(\lambda)\right)
\end{array}\right) d \lambda .
$$

### 9.7. The spectra of one-dimensional Schrödinger operators

In this section we want to look at the case of one-dimensional Schrödinger operators; that is, $r=p=1$ on $(a, b)=(0, \infty)$.

Recall that

$$
\begin{equation*}
H_{0}=-\frac{d^{2}}{d x^{2}}, \quad \mathfrak{D}\left(H_{0}\right)=H^{2}(\mathbb{R}) \tag{9.113}
\end{equation*}
$$

is self-adjoint and

$$
\begin{equation*}
q_{H_{0}}(f)=\left\|f^{\prime}\right\|^{2}, \quad \mathfrak{Q}\left(H_{0}\right)=H^{1}(\mathbb{R}) \tag{9.114}
\end{equation*}
$$

Hence we can try to apply the results from Chapter 6 . We begin with a simple estimate:
Lemma 9.32. Suppose $f \in H^{1}(0,1)$. Then

$$
\begin{equation*}
\sup _{x \in[0,1]}|f(x)|^{2} \leq \varepsilon \int_{0}^{1}\left|f^{\prime}(x)\right|^{2} d x+\left(1+\frac{1}{\varepsilon}\right) \int_{0}^{1}|f(x)|^{2} d x \tag{9.115}
\end{equation*}
$$

for every $\varepsilon>0$.
Proof. First note that

$$
\begin{aligned}
|f(x)|^{2} & =|f(c)|^{2}+2 \int_{c}^{x} \operatorname{Re}\left(f(t)^{*} f^{\prime}(t)\right) d t \leq|f(c)|^{2}+2 \int_{0}^{1}\left|f(t) f^{\prime}(t)\right| d t \\
& \leq|f(c)|^{2}+\varepsilon \int_{0}^{1}\left|f^{\prime}(t)\right|^{2} d t+\frac{1}{\varepsilon} \int_{0}^{1}|f(t)|^{2} d t
\end{aligned}
$$

for any $c \in[0,1]$. But by the mean value theorem there is a $c \in(0,1)$ such that $|f(c)|^{2}=\int_{0}^{1}|f(t)|^{2} d t$.

As a consequence we obtain
Lemma 9.33. Suppose $q \in L_{\text {loc }}^{2}(\mathbb{R})$ and

$$
\begin{equation*}
\sup _{n \in \mathbb{Z}} \int_{n}^{n+1}|q(x)|^{2} d x<\infty \tag{9.116}
\end{equation*}
$$

Then $q$ is relatively bounded with respect to $H_{0}$ with bound zero.
Similarly, if $q \in L_{\text {loc }}^{1}(\mathbb{R})$ and

$$
\begin{equation*}
\sup _{n \in \mathbb{Z}} \int_{n}^{n+1}|q(x)| d x<\infty . \tag{9.117}
\end{equation*}
$$

Then $q$ is relatively form bounded with respect to $H_{0}$ with bound zero.
Proof. Let $Q$ be in $L_{l o c}^{2}(\mathbb{R})$ and abbreviate $M=\sup _{n \in \mathbb{Z}} \int_{n}^{n+1}|Q(x)|^{2} d x$. Using the previous lemma, we have for $f \in H^{1}(\mathbb{R})$ that

$$
\begin{aligned}
\|Q f\|^{2} & \leq \sum_{n \in \mathbb{Z}} \int_{n}^{n+1}|Q(x) f(x)|^{2} d x \leq M \sum_{n \in \mathbb{Z}} \sup _{x \in[n, n+1]}|f(x)|^{2} \\
& \leq M\left(\varepsilon \int_{n}^{n+1}\left|f^{\prime}(x)\right|^{2} d x+\left(1+\frac{1}{\varepsilon}\right) \int_{n}^{n+1}|f(x)|^{2} d x\right) \\
& =M\left(\varepsilon\left\|f^{\prime}\right\|^{2}+\left(1+\frac{1}{\varepsilon}\right)\|f\|^{2}\right) .
\end{aligned}
$$

Choosing $Q=|q|^{1 / 2}$, this already proves the form case since $\left\|f^{\prime}\right\|^{2}=q_{H_{0}}(f)$. Choosing $Q=q$ and observing $q_{H_{0}}(f)=\left\langle f, H_{0} f\right\rangle \leq\left\|H_{0} f\right\|\|f\|$ for $f \in$ $H^{2}(\mathbb{R})$ shows the operator case.

Hence in both cases $H_{0}+q$ is a well-defined (semi-bounded) operator defined as operator sum on $\mathfrak{D}\left(H_{0}+q\right)=\mathfrak{D}\left(H_{0}\right)=H^{2}(\mathbb{R})$ in the first case and as form sum on $\mathfrak{Q}\left(H_{0}+q\right)=\mathfrak{Q}\left(H_{0}\right)=H^{1}(\mathbb{R})$ in the second case. Note also that the first case implies the second one since by Cauchy-Schwarz we have

$$
\begin{equation*}
\int_{n}^{n+1}|q(x)| d x \leq \int_{n}^{n+1}|q(x)|^{2} d x \tag{9.118}
\end{equation*}
$$

This is not too surprising since we already know how to turn $H_{0}+q$ into a self-adjoint operator without imposing any conditions on $q$ (except for $\left.L_{l o c}^{1}(\mathbb{R})\right)$ at all. However, we get at least a simple description of the (form) domains and by requiring a bit more, we can even compute the essential spectrum of the perturbed operator.
Lemma 9.34. Suppose $q \in L^{1}(\mathbb{R})$. Then the resolvent difference of $H_{0}$ and $H_{0}+q$ is trace class.

Proof. Using $G_{0}(z, x, x)=1 /(2 \sqrt{-z})$, Lemma 9.12 implies that $|q|^{1 / 2} R_{H_{0}}(z)$ is Hilbert-Schmidt and hence the result follows from Lemma 6.29.

Lemma 9.35. Suppose $q \in L_{l o c}^{1}(\mathbb{R})$ and

$$
\begin{equation*}
\lim _{|n| \rightarrow \infty} \int_{n}^{n+1}|q(x)| d x=0 \tag{9.119}
\end{equation*}
$$

Then $R_{H_{0}+q}(z)-R_{H_{0}}(z)$ is compact and hence $\sigma_{\text {ess }}\left(H_{0}+q\right)=\sigma_{\text {ess }}\left(H_{0}\right)=$ $[0, \infty)$.

Proof. By Weyl's theorem it suffices to show that the resolvent difference is compact. Let $q_{n}(x)=q(x) \chi_{\mathbb{R} \backslash[-n, n]}(x)$. Then $R_{H_{0}+q}(z)-R_{H_{0}+q_{n}}(z)$ is trace class, which can be shown as in the previous theorem since $q-q_{n}$ has compact support (no information on the corresponding diagonal Green's function is needed since by continuity it is bounded on every compact set). Moreover, by the proof of Lemma 9.33, $q_{n}$ is form bounded with respect to $H_{0}$ with constants $a=M_{n}$ and $b=2 M_{n}$, where $M_{n}=\sup _{|m| \geq n} \int_{m}^{m+1}|q(x)|^{2} d x$. Hence by Theorem 6.25 we see

$$
R_{H_{0}+q_{n}}(-\lambda)=R_{H_{0}}(-\lambda)^{1 / 2}\left(1-C_{q_{n}}(\lambda)\right)^{-1} R_{H_{0}}(-\lambda)^{1 / 2}, \quad \lambda>2
$$

with $\left\|C_{q_{n}}(\lambda)\right\| \leq M_{n}$. So we conclude
$R_{H_{0}+q_{n}}(-\lambda)-R_{H_{0}}(-\lambda)=-R_{H_{0}}(-\lambda)^{1 / 2} C_{q_{n}}(\lambda)\left(1-C_{q_{n}}(\lambda)\right)^{-1} R_{H_{0}}(-\lambda)^{1 / 2}$,
$\lambda>2$, which implies that the sequence of compact operators $R_{H_{0}+q}(-\lambda)-$ $R_{H_{0}+q_{n}}(-\lambda)$ converges to $R_{H_{0}+q}(-\lambda)-R_{H_{0}}(-\lambda)$ in norm, which implies that the limit is also compact and finishes the proof.

Using Lemma 6.23, respectively, Corollary 6.27 , we even obtain
Corollary 9.36. Let $q=q_{1}+q_{2}$ where $q_{1}$ and $q_{2}$ satisfy the assumptions of Lemma 9.33 and Lemma 9.35, respectively. Then $H_{0}+q_{1}+q_{2}$ is self-adjoint and $\sigma_{\text {ess }}\left(H_{0}+q_{1}+q_{2}\right)=\sigma_{\text {ess }}\left(H_{0}+q_{1}\right)$.

This result applies for example in the case where $q_{2}$ is a decaying perturbation of a periodic potential $q_{1}$.

Finally we turn to the absolutely continuous spectrum.
Lemma 9.37. Suppose $q=q_{1}+q_{2}$, where $q_{1} \in L^{1}(0, \infty)$ and $q_{2} \in A C[0, \infty)$ with $q_{2}^{\prime} \in L^{1}(0, \infty)$ and $\lim _{x \rightarrow \infty} q_{2}(x)=0$. Then there are two solutions $u_{ \pm}(\lambda, x)$ of $\tau u=\lambda u, \lambda>0$, of the form

$$
\begin{equation*}
u_{ \pm}(\lambda, x)=(1+o(1)) u_{0, \pm}(\lambda, x), \quad u_{ \pm}^{\prime}(\lambda, x)=(1+o(1)) u_{0, \pm}^{\prime}(\lambda, x) \tag{9.120}
\end{equation*}
$$

as $x \rightarrow \infty$, where

$$
\begin{equation*}
u_{0, \pm}(\lambda, x)=\exp \left( \pm \mathrm{i} \int_{0}^{x} \sqrt{\lambda-q_{2}(y)} d y\right) \tag{9.121}
\end{equation*}
$$

Proof. We will omit the dependence on $\lambda$ for notational simplicity. Moreover, we will choose $x$ so large that $W_{x}\left(u_{-}, u_{+}\right)=2 \mathrm{i} \sqrt{\lambda-q_{2}(x)} \neq 0$. Write

$$
\underline{u}(x)=U_{0}(x) \underline{a}(x), \quad U_{0}(x)=\left(\begin{array}{ll}
u_{0,+}(x) & u_{0,+}(x) \\
u_{0,-}^{\prime}(x) & u_{0,-}^{\prime}(x)
\end{array}\right), \quad \underline{a}(x)=\binom{a_{+}(x)}{a_{-}(x)} .
$$

Then

$$
\begin{aligned}
\underline{u}^{\prime}(x)= & \left(\begin{array}{cc}
0 & 1 \\
q(x)-\lambda & 0
\end{array}\right) \underline{u}(x) \\
& +\left(\begin{array}{cc}
0 & 0 \\
q_{+}(x) u_{0,+}(x) & q_{-}(x) u_{0,-}(x)
\end{array}\right) \underline{a}(x)+U_{0}(x) \underline{a}^{\prime}(x),
\end{aligned}
$$

where

$$
q_{ \pm}(x)=q_{1}(x) \pm \mathrm{i} \frac{q_{2}^{\prime}(x)}{\sqrt{\lambda-q_{2}(x)}} .
$$

Hence $u(x)$ will solve $\tau u=\lambda u$ if

$$
\underline{a}^{\prime}(x)=\frac{1}{W_{x}\left(u_{-}, u_{+}\right)}\left(\begin{array}{cc}
q_{+}(x) & q_{-}(x) u_{0,-}(x)^{2} \\
-q_{+}(x) u_{0,+}(x)^{2} & -q_{-}(x)
\end{array}\right) \underline{a}(x) .
$$

Since the coefficient matrix of this linear system is integrable, the claim follows by a simple application of Gronwall's inequality.

Theorem 9.38 (Weidmann). Let $q_{1}$ and $q_{2}$ be as in the previous lemma and suppose $q=q_{1}+q_{2}$ satisfies the assumptions of Lemma 9.35. Let $H=H_{0}+q_{1}+q_{2}$. Then $\sigma_{a c}(H)=[0, \infty), \sigma_{s c}(H)=\emptyset$, and $\sigma_{p}(H) \subseteq(-\infty, 0]$.

Proof. By the previous lemma there is no subordinate solution for $\lambda>0$ on $(0, \infty)$ and hence $0<\operatorname{Im}\left(m_{b}(\lambda+\mathrm{i} 0)\right)<\infty$. Similarly, there is no subordinate solution $(-\infty, 0)$ and hence $0<\operatorname{Im}\left(m_{a}(\lambda+\mathrm{i} 0)\right)<\infty$. Thus the same is true for the diagonal entries $M_{j j}(z)$ of the Weyl $M$-matrix, $0<\operatorname{Im}\left(M_{j j}(\lambda+\right.$ i0)) $<\infty$, and hence $d \mu$ is purely absolutely continuous on $(0, \infty)$. Since $\sigma_{\text {ess }}(H)=[0, \infty)$, we conclude $\sigma_{a c}(H)=[0, \infty)$ and $\sigma_{s c}(H) \subseteq\{0\}$. Since the singular continuous part cannot live on a single point, we are done.

Note that the same results hold for operators on $[0, \infty)$ rather than $\mathbb{R}$. Moreover, observe that the conditions from Lemma 9.37 are only imposed near $+\infty$ but not near $-\infty$. The conditions from Lemma 9.35 are only used to ensure that there is no essential spectrum in $(-\infty, 0)$.

Having dealt with the essential spectrum, let us next look at the discrete spectrum. In the case of decaying potentials, as in the previous theorem, one key question is if the number of eigenvalues below the essential spectrum is finite or not.

As preparation, we shall prove Sturm's comparison theorem:

Theorem 9.39 (Sturm). Let $\tau_{0}$, $\tau_{1}$ be associated with $q_{0} \geq q_{1}$ on $(a, b)$, respectively. Let $(c, d) \subseteq(a, b)$ and $\tau_{0} u=0, \tau_{1} v=0$. Suppose at each end of $(c, d)$ either $W_{x}(u, v)=0$ or, if $c, d \in(a, b), u=0$. Then $v$ is either $a$ multiple of $u$ in $(c, d)$ or $v$ must vanish at some point in $(c, d)$.

Proof. By decreasing $d$ to the first zero of $u$ in $(c, d]$ (and perhaps flipping signs), we can suppose $u>0$ on $(c, d)$. If $v$ has no zeros in $(c, d)$, we can suppose $v>0$ on $(c, d)$ again by perhaps flipping signs. At each endpoint, $W(u, v)$ vanishes or else $u=0, v>0$, and $u^{\prime}(c)>0\left(\right.$ or $\left.u^{\prime}(d)<0\right)$. Thus, $W_{c}(u, v) \leq 0, W_{d}(u, v) \geq 0$. But this is inconsistent with

$$
\begin{equation*}
W_{d}(u, v)-W_{c}(u, v)=\int_{c}^{d}\left(q_{0}(t)-q_{1}(t)\right) u(t) v(t) d t \tag{9.122}
\end{equation*}
$$

unless both sides vanish.
In particular, choosing $q_{0}=q-\lambda_{0}$ and $q_{1}=q-\lambda_{1}$, this result holds for solutions of $\tau u=\lambda_{0} u$ and $\tau v=\lambda_{1} v$.

Now we can prove
Theorem 9.40. Suppose $q$ satisfies (9.117) such that $H$ is semi-bounded and $\mathfrak{Q}(H)=H^{1}(\mathbb{R})$. Let $\lambda_{0}<\cdots<\lambda_{n}<\cdots$ be its eigenvalues below the essential spectrum and $\psi_{0}, \ldots, \psi_{n}, \ldots$ the corresponding eigenfunctions. Then $\psi_{n}$ has $n$ zeros.

Proof. We first prove that $\psi_{n}$ has at least $n$ zeros and then that if $\psi_{n}$ has $m$ zeros, then $\left(-\infty, \lambda_{n}\right]$ has at least $(m+1)$ eigenvalues. If $\psi_{n}$ has $m$ zeros at $x_{1}, x_{2}, \ldots, x_{m}$ and we let $x_{0}=a, x_{m+1}=b$, then by Theorem $9.39, \psi_{n+1}$ must have at least one zero in each of $\left(x_{0}, x_{1}\right),\left(x_{1}, x_{2}\right), \ldots,\left(x_{m}, x_{m+1}\right)$; that is, $\psi_{n+1}$ has at least $m+1$ zeros. It follows by induction that $\psi_{n}$ has at least $n$ zeros.

On the other hand, if $\psi_{n}$ has $m$ zeros $x_{1}, \ldots, x_{m}$, define

$$
\eta_{j}(x)=\left\{\begin{array}{ll}
\psi_{n}(x), & x_{j} \leq x \leq x_{j+1},  \tag{9.123}\\
0 & \text { otherwise }
\end{array} \quad j=0, \ldots, m\right.
$$

where we set $x_{0}=-\infty$ and $x_{m+1}=\infty$. Then $\eta_{j}$ is in the form domain of $H$ and satisfies $\left\langle\eta_{j}, H \eta_{j}\right\rangle=\lambda_{n}\left\|\eta_{j}\right\|^{2}$. Hence if $\eta=\sum_{j=0}^{m} c_{j} \eta_{j}$, then $\langle\eta, H \eta\rangle=\lambda_{n}\|\eta\|^{2}$ and it follows by Theorem 4.12 (i) that there are at least $m+1$ eigenvalues in $\left(-\infty, \lambda_{n}\right]$.

Note that by Theorem 9.39 , the zeros of $\psi_{n}$ interlace the zeros of $\psi_{n}$. The second part of the proof also shows
Corollary 9.41. Let $H$ be as in the previous theorem. If the Weyl solution $u_{ \pm}(\lambda,$.$) has m$ zeros, then $\operatorname{dim} \operatorname{Ran}_{(-\infty, \lambda)}(H) \geq m$. In particular, $\lambda$ below the spectrum of $H$ implies that $u_{ \pm}(\lambda,$.$) has no zeros.$

The equation $(\tau-\lambda) u$ is called oscillating if one solution has an infinite number of zeros. Theorem 9.39 implies that this is then true for all solutions. By our previous considerations this is the case if and only if $\sigma(H)$ has infinitely many points below $\lambda$. Hence it remains to find a good oscillation criterion.

Theorem 9.42 (Kneser). Consider $q$ on $(0, \infty)$. Then

$$
\begin{equation*}
\liminf _{x \rightarrow \infty}\left(x^{2} q(x)\right)>-\frac{1}{4} \text { implies nonoscillation of } \tau \text { near } \infty \tag{9.124}
\end{equation*}
$$

and

$$
\begin{equation*}
\limsup _{x \rightarrow \infty}\left(x^{2} q(x)\right)<-\frac{1}{4} \text { implies oscillation of } \tau \text { near } \infty . \tag{9.125}
\end{equation*}
$$

Proof. The key idea is that the equation

$$
\tau_{0}=-\frac{d^{2}}{d x^{2}}+\frac{\mu}{x^{2}}
$$

is of Euler type. Hence it is explicitly solvable with a fundamental system given by

$$
x^{\frac{1}{2} \pm \sqrt{\mu+\frac{1}{4}}} .
$$

There are two cases to distinguish. If $\mu \geq-1 / 4$, all solutions are nonoscillatory. If $\mu<-1 / 4$, one has to take real/imaginary parts and all solutions are oscillatory. Hence a straightforward application of Sturm's comparison theorem between $\tau_{0}$ and $\tau$ yields the result.

Corollary 9.43. Suppose $q$ satisfies (9.117). Then $H$ has finitely many eigenvalues below the infimum of the essential spectrum 0 if

$$
\begin{equation*}
\lim _{|x| \rightarrow \infty} \inf \left(x^{2} q(x)\right)>-\frac{1}{4} \tag{9.126}
\end{equation*}
$$

and infinitely many if

$$
\begin{equation*}
\lim _{|x| \rightarrow \infty} \sup \left(x^{2} q(x)\right)<-\frac{1}{4} . \tag{9.127}
\end{equation*}
$$

Problem 9.18. Show that if $q$ is relatively bounded with respect to $H_{0}$, then necessarily $q \in L_{\text {loc }}^{2}(\mathbb{R})$ and (9.116) holds. Similarly, if $q$ is relatively form bounded with respect to $H_{0}$, then necessarily $q \in L_{\text {loc }}^{1}(\mathbb{R})$ and (9.117) holds.

Problem 9.19. Suppose $q \in L^{1}(\mathbb{R})$ and consider $H=-\frac{d^{2}}{d x^{2}}+q$. Show that $\inf \sigma(H) \leq \int_{\mathbb{R}} q(x) d x$. In particular, there is at least one eigenvalue below the essential spectrum if $\int_{\mathbb{R}} q(x) d x<0$. (Hint: Let $\varphi \in C_{c}^{\infty}(\mathbb{R})$ with $\varphi(x)=1$ for $|x| \leq 1$ and investigate $q_{H}\left(\varphi_{n}\right)$, where $\varphi_{n}(x)=\varphi(x / n)$.)

## One-particle Schrödinger operators

### 10.1. Self-adjointness and spectrum

Our next goal is to apply these results to Schrödinger operators. The Hamiltonian of one particle in $d$ dimensions is given by

$$
\begin{equation*}
H=H_{0}+V, \tag{10.1}
\end{equation*}
$$

where $V: \mathbb{R}^{d} \rightarrow \mathbb{R}$ is the potential energy of the particle. We are mainly interested in the case $1 \leq d \leq 3$ and want to find classes of potentials which are relatively bounded, respectively, relatively compact. To do this, we need a better understanding of the functions in the domain of $H_{0}$.

Lemma 10.1. Suppose $n \leq 3$ and $\psi \in H^{2}\left(\mathbb{R}^{n}\right)$. Then $\psi \in C_{\infty}\left(\mathbb{R}^{n}\right)$ and for any $a>0$ there is a $b>0$ such that

$$
\begin{equation*}
\|\psi\|_{\infty} \leq a\left\|H_{0} \psi\right\|+b\|\psi\| . \tag{10.2}
\end{equation*}
$$

Proof. The important observation is that $\left(p^{2}+\gamma^{2}\right)^{-1} \in L^{2}\left(\mathbb{R}^{n}\right)$ if $n \leq 3$. Hence, since $\left(p^{2}+\gamma^{2}\right) \hat{\psi} \in L^{2}\left(\mathbb{R}^{n}\right)$, the Cauchy-Schwarz inequality

$$
\begin{aligned}
\|\hat{\psi}\|_{1} & =\left\|\left(p^{2}+\gamma^{2}\right)^{-1}\left(p^{2}+\gamma^{2}\right) \hat{\psi}(p)\right\|_{1} \\
& \leq\left\|\left(p^{2}+\gamma^{2}\right)^{-1}\right\|\left\|\left(p^{2}+\gamma^{2}\right) \hat{\psi}(p)\right\|
\end{aligned}
$$

shows $\hat{\psi} \in L^{1}\left(\mathbb{R}^{n}\right)$. But now everything follows from the Riemann-Lebesgue lemma, that is,

$$
\begin{aligned}
\|\psi\|_{\infty} & \leq(2 \pi)^{-n / 2}\left\|\left(p^{2}+\gamma^{2}\right)^{-1}\right\|\left(\left\|p^{2} \hat{\psi}(p)\right\|+\gamma^{2}\|\hat{\psi}(p)\|\right) \\
& =(\gamma / 2 \pi)^{n / 2}\left\|\left(p^{2}+1\right)^{-1}\right\|\left(\gamma^{-2}\left\|H_{0} \psi\right\|+\|\psi\|\right),
\end{aligned}
$$

which finishes the proof.

Now we come to our first result.
Theorem 10.2. Let $V$ be real-valued and $V \in L_{\infty}^{\infty}\left(\mathbb{R}^{n}\right)$ if $n>3$ and $V \in$ $L_{\infty}^{\infty}\left(\mathbb{R}^{n}\right)+L^{2}\left(\mathbb{R}^{n}\right)$ if $n \leq 3$. Then $V$ is relatively compact with respect to $H_{0}$. In particular,

$$
\begin{equation*}
H=H_{0}+V, \quad \mathfrak{D}(H)=H^{2}\left(\mathbb{R}^{n}\right) \tag{10.3}
\end{equation*}
$$

is self-adjoint, bounded from below and

$$
\begin{equation*}
\sigma_{e s s}(H)=[0, \infty) . \tag{10.4}
\end{equation*}
$$

Moreover, $C_{c}^{\infty}\left(\mathbb{R}^{n}\right)$ is a core for $H$.
Proof. Our previous lemma shows $\mathfrak{D}\left(H_{0}\right) \subseteq \mathfrak{D}(V)$. Moreover, invoking Lemma 7.11 with $f(p)=\left(p^{2}-z\right)^{-1}$ and $g(x)=V(x)$ (note that $f \in$ $L_{\infty}^{\infty}\left(\mathbb{R}^{n}\right) \cap L^{2}\left(\mathbb{R}^{n}\right)$ for $n \leq 3$ ) shows that $V$ is relatively compact. Since $C_{c}^{\infty}\left(\mathbb{R}^{n}\right)$ is a core for $H_{0}$ by Lemma 7.9, the same is true for $H$ by the Kato-Rellich theorem.

Observe that since $C_{c}^{\infty}\left(\mathbb{R}^{n}\right) \subseteq \mathfrak{D}\left(H_{0}\right)$, we must have $V \in L_{\text {loc }}^{2}\left(\mathbb{R}^{n}\right)$ if $\mathfrak{D}(V) \subseteq \mathfrak{D}\left(H_{0}\right)$.

### 10.2. The hydrogen atom

We begin with the simple model of a single electron in $\mathbb{R}^{3}$ moving in the external potential $V$ generated by a nucleus (which is assumed to be fixed at the origin). If one takes only the electrostatic force into account, then $V$ is given by the Coulomb potential and the corresponding Hamiltonian is given by

$$
\begin{equation*}
H^{(1)}=-\Delta-\frac{\gamma}{|x|}, \quad \mathfrak{D}\left(H^{(1)}\right)=H^{2}\left(\mathbb{R}^{3}\right) . \tag{10.5}
\end{equation*}
$$

If the potential is attracting, that is, if $\gamma>0$, then it describes the hydrogen atom and is probably the most famous model in quantum mechanics.

We have chosen as domain $\mathfrak{D}\left(H^{(1)}\right)=\mathfrak{D}\left(H_{0}\right) \cap \mathfrak{D}\left(\frac{1}{|x|}\right)=\mathfrak{D}\left(H_{0}\right)$ and by Theorem 10.2 we conclude that $H^{(1)}$ is self-adjoint. Moreover, Theorem 10.2 also tells us

$$
\begin{equation*}
\sigma_{\text {ess }}\left(H^{(1)}\right)=[0, \infty) \tag{10.6}
\end{equation*}
$$

and that $H^{(1)}$ is bounded from below,

$$
\begin{equation*}
E_{0}=\inf \sigma\left(H^{(1)}\right)>-\infty \tag{10.7}
\end{equation*}
$$

If $\gamma \leq 0$, we have $H^{(1)} \geq 0$ and hence $E_{0}=0$, but if $\gamma>0$, we might have $E_{0}<0$ and there might be some discrete eigenvalues below the essential spectrum.

In order to say more about the eigenvalues of $H^{(1)}$, we will use the fact that both $H_{0}$ and $V^{(1)}=-\gamma /|x|$ have a simple behavior with respect to scaling. Consider the dilation group

$$
\begin{equation*}
U(s) \psi(x)=\mathrm{e}^{-n s / 2} \psi\left(\mathrm{e}^{-s} x\right), \quad s \in \mathbb{R}, \tag{10.8}
\end{equation*}
$$

which is a strongly continuous one-parameter unitary group. The generator can be easily computed:

$$
\begin{equation*}
D \psi(x)=\frac{1}{2}(x p+p x) \psi(x)=\left(x p-\frac{\mathrm{i} n}{2}\right) \psi(x), \quad \psi \in \mathcal{S}\left(\mathbb{R}^{n}\right) \tag{10.9}
\end{equation*}
$$

Now let us investigate the action of $U(s)$ on $H^{(1)}$ :

$$
\begin{equation*}
H^{(1)}(s)=U(-s) H^{(1)} U(s)=\mathrm{e}^{-2 s} H_{0}+\mathrm{e}^{-s} V^{(1)}, \quad \mathfrak{D}\left(H^{(1)}(s)\right)=\mathfrak{D}\left(H^{(1)}\right) . \tag{10.10}
\end{equation*}
$$

Now suppose $H \psi=\lambda \psi$. Then

$$
\begin{equation*}
\langle\psi,[U(s), H] \psi\rangle=\langle U(-s) \psi, H \psi\rangle-\langle H \psi, U(s) \psi\rangle=0 \tag{10.11}
\end{equation*}
$$

and hence

$$
\begin{align*}
0 & =\lim _{s \rightarrow 0} \frac{1}{s}\langle\psi,[U(s), H] \psi\rangle=\lim _{s \rightarrow 0}\left\langle U(-s) \psi, \frac{H-H(s)}{s} \psi\right\rangle \\
& =\left\langle\psi,\left(2 H_{0}+V^{(1)}\right) \psi\right\rangle . \tag{10.12}
\end{align*}
$$

Thus we have proven the virial theorem.
Theorem 10.3. Suppose $H=H_{0}+V$ with $U(-s) V U(s)=\mathrm{e}^{-s} V$. Then any normalized eigenfunction $\psi$ corresponding to an eigenvalue $\lambda$ satisfies

$$
\begin{equation*}
\lambda=-\left\langle\psi, H_{0} \psi\right\rangle=\frac{1}{2}\langle\psi, V \psi\rangle . \tag{10.13}
\end{equation*}
$$

In particular, all eigenvalues must be negative.
This result even has some further consequences for the point spectrum of $H^{(1)}$.

Corollary 10.4. Suppose $\gamma>0$. Then

$$
\begin{equation*}
\sigma_{p}\left(H^{(1)}\right)=\sigma_{d}\left(H^{(1)}\right)=\left\{E_{j-1}\right\}_{j \in \mathbb{N}_{0}}, \quad E_{0}<E_{j}<E_{j+1}<0, \tag{10.14}
\end{equation*}
$$

with $\lim _{j \rightarrow \infty} E_{j}=0$.
Proof. Choose $\psi \in C_{c}^{\infty}(\mathbb{R} \backslash\{0\})$ and set $\psi(s)=U(-s) \psi$. Then

$$
\left\langle\psi(s), H^{(1)} \psi(s)\right\rangle=\mathrm{e}^{-2 s}\left\langle\psi, H_{0} \psi\right\rangle+\mathrm{e}^{-s}\left\langle\psi, V^{(1)} \psi\right\rangle
$$

which is negative for $s$ large. Now choose a sequence $s_{n} \rightarrow \infty$ such that we have $\operatorname{supp}\left(\psi\left(s_{n}\right)\right) \cap \operatorname{supp}\left(\psi\left(s_{m}\right)\right)=\emptyset$ for $n \neq m$. Then Theorem 4.12 (i) shows that $\operatorname{rank}\left(P_{H^{(1)}}((-\infty, 0))\right)=\infty$. Since each eigenvalue $E_{j}$ has finite multiplicity (it lies in the discrete spectrum), there must be an infinite number of eigenvalues which accumulate at 0 .

If $\gamma \leq 0$, we have $\sigma_{d}\left(H^{(1)}\right)=\emptyset$ since $H^{(1)} \geq 0$ in this case.
Hence we have obtained quite a complete picture of the spectrum of $H^{(1)}$. Next, we could try to compute the eigenvalues of $H^{(1)}$ (in the case $\gamma>0$ ) by solving the corresponding eigenvalue equation, which is given by the partial differential equation

$$
\begin{equation*}
-\Delta \psi(x)-\frac{\gamma}{|x|} \psi(x)=\lambda \psi(x) . \tag{10.15}
\end{equation*}
$$

For a general potential this is hopeless, but in our case we can use the rotational symmetry of our operator to reduce our partial differential equation to ordinary ones.

First of all, it suggests itself to switch from Cartesian coordinates $x=$ $\left(x_{1}, x_{2}, x_{3}\right)$ to spherical coordinates $(r, \theta, \varphi)$ defined by

$$
\begin{equation*}
x_{1}=r \sin (\theta) \cos (\varphi), \quad x_{2}=r \sin (\theta) \sin (\varphi), \quad x_{3}=r \cos (\theta), \tag{10.16}
\end{equation*}
$$

where $r \in[0, \infty), \theta \in[0, \pi]$, and $\varphi \in(-\pi, \pi]$. This change of coordinates corresponds to a unitary transform

$$
\begin{equation*}
L^{2}\left(\mathbb{R}^{3}\right) \rightarrow L^{2}\left((0, \infty), r^{2} d r\right) \otimes L^{2}((0, \pi), \sin (\theta) d \theta) \otimes L^{2}((0,2 \pi), d \varphi) \tag{10.17}
\end{equation*}
$$

In these new coordinates $(r, \theta, \varphi)$ our operator reads

$$
\begin{equation*}
H^{(1)}=-\frac{1}{r^{2}} \frac{\partial}{\partial r} r^{2} \frac{\partial}{\partial r}+\frac{1}{r^{2}} L^{2}+V(r), \quad V(r)=-\frac{\gamma}{r}, \tag{10.18}
\end{equation*}
$$

where

$$
\begin{equation*}
L^{2}=L_{1}^{2}+L_{2}^{2}+L_{3}^{2}=-\frac{1}{\sin (\theta)} \frac{\partial}{\partial \theta} \sin (\theta) \frac{\partial}{\partial \theta}-\frac{1}{\sin (\theta)^{2}} \frac{\partial^{2}}{\partial \varphi^{2}} \tag{10.19}
\end{equation*}
$$

(Recall the angular momentum operators $L_{j}$ from Section 8.2.)
Making the product ansatz (separation of variables)

$$
\begin{equation*}
\psi(r, \theta, \varphi)=R(r) \Theta(\theta) \Phi(\varphi) \tag{10.20}
\end{equation*}
$$

we obtain the three Sturm-Liouville equations

$$
\begin{align*}
\left(-\frac{1}{r^{2}} \frac{d}{d r} r^{2} \frac{d}{d r}+\frac{l(l+1)}{r^{2}}+V(r)\right) R(r) & =\lambda R(r) \\
\frac{1}{\sin (\theta)}\left(-\frac{d}{d \theta} \sin (\theta) \frac{d}{d \theta}+\frac{m^{2}}{\sin (\theta)}\right) \Theta(\theta) & =l(l+1) \Theta(\theta) \\
-\frac{d^{2}}{d \varphi^{2}} \Phi(\varphi) & =m^{2} \Phi(\varphi) \tag{10.21}
\end{align*}
$$

The form chosen for the constants $l(l+1)$ and $m^{2}$ is for convenience later on. These equations will be investigated in the following sections.

Problem 10.1. Generalize the virial theorem to the case $U(-s) V U(s)=$ $\mathrm{e}^{-\alpha s} V, \alpha \in \mathbb{R} \backslash\{0\}$. What about Corollary 10.4?

### 10.3. Angular momentum

We start by investigating the equation for $\Phi(\varphi)$ which is associated with the Sturm-Liouville equation

$$
\begin{equation*}
\tau \Phi=-\Phi^{\prime \prime}, \quad I=(0,2 \pi) \tag{10.22}
\end{equation*}
$$

Since we want $\psi$ defined via (10.20) to be in the domain of $H_{0}$ (in particular continuous), we choose periodic boundary conditions the Sturm-Liouville equation

$$
\begin{align*}
A \Phi=\tau \Phi, \quad \mathfrak{D}(A)=\left\{\Phi \in L^{2}(0,2 \pi) \mid\right. & \Phi \in A C^{1}[0,2 \pi], \\
& \left.\Phi(0)=\Phi(2 \pi), \Phi^{\prime}(0)=\Phi^{\prime}(2 \pi)\right\} . \tag{10.23}
\end{align*}
$$

From our analysis in Section 9.1 we immediately obtain
Theorem 10.5. The operator $A$ defined via (10.22) is self-adjoint. Its spectrum is purely discrete, that is,

$$
\begin{equation*}
\sigma(A)=\sigma_{d}(A)=\left\{m^{2} \mid m \in \mathbb{Z}\right\} \tag{10.24}
\end{equation*}
$$

and the corresponding eigenfunctions

$$
\begin{equation*}
\Phi_{m}(\varphi)=\frac{1}{\sqrt{2 \pi}} \mathrm{e}^{\mathrm{i} m \varphi}, \quad m \in \mathbb{Z}, \tag{10.25}
\end{equation*}
$$

form an orthonormal basis for $L^{2}(0,2 \pi)$.
Note that except for the lowest eigenvalue, all eigenvalues are twice degenerate.

We note that this operator is essentially the square of the angular momentum in the third coordinate direction, since in polar coordinates

$$
\begin{equation*}
L_{3}=\frac{1}{\mathrm{i}} \frac{\partial}{\partial \varphi} . \tag{10.26}
\end{equation*}
$$

Now we turn to the equation for $\Theta(\theta)$ :

$$
\begin{equation*}
\tau_{m} \Theta(\theta)=\frac{1}{\sin (\theta)}\left(-\frac{d}{d \theta} \sin (\theta) \frac{d}{d \theta}+\frac{m^{2}}{\sin (\theta)}\right) \Theta(\theta), \quad I=(0, \pi), m \in \mathbb{N}_{0} \tag{10.27}
\end{equation*}
$$

For the investigation of the corresponding operator we use the unitary transform

$$
\begin{equation*}
L^{2}((0, \pi), \sin (\theta) d \theta) \rightarrow L^{2}((-1,1), d x), \quad \Theta(\theta) \mapsto f(x)=\Theta(\arccos (x)) \tag{10.28}
\end{equation*}
$$

The operator $\tau$ transforms to the somewhat simpler form

$$
\begin{equation*}
\tau_{m}=-\frac{d}{d x}\left(1-x^{2}\right) \frac{d}{d x}-\frac{m^{2}}{1-x^{2}} . \tag{10.29}
\end{equation*}
$$

The corresponding eigenvalue equation

$$
\begin{equation*}
\tau_{m} u=l(l+1) u \tag{10.30}
\end{equation*}
$$

is the associated Legendre equation. For $l \in \mathbb{N}_{0}$ it is solved by the associated Legendre functions [1, (8.6.6)]

$$
\begin{equation*}
P_{l}^{m}(x)=(-1)^{m}\left(1-x^{2}\right)^{m / 2} \frac{d^{m}}{d x^{m}} P_{l}(x), \quad|m| \leq l \tag{10.31}
\end{equation*}
$$

where the

$$
\begin{equation*}
P_{l}(x)=\frac{1}{2^{l} l!} \frac{d^{l}}{d x^{l}}\left(x^{2}-1\right)^{l}, \quad l \in \mathbb{N}_{0} \tag{10.32}
\end{equation*}
$$

are the Legendre polynomials [1, (8.6.18)] (Problem 10.2). Moreover, note that the $P_{l}(x)$ are (nonzero) polynomials of degree $l$ and since $\tau_{m}$ depends only on $m^{2}$, there must be a relation between $P_{l}^{m}(x)$ and $P_{l}^{-m}(x)$. In fact, (Problem 10.3)

$$
\begin{equation*}
P_{l}^{-m}(x)=(-1)^{m} \frac{(l+m)!}{(l-m)!} P_{l}^{m} \tag{10.33}
\end{equation*}
$$

A second, linearly independent, solution is given by

$$
\begin{equation*}
Q_{l}^{m}(x)=P_{l}^{m}(x) \int_{0}^{x} \frac{d t}{\left(1-t^{2}\right) P_{l}^{m}(t)^{2}} \tag{10.34}
\end{equation*}
$$

In fact, for every Sturm-Liouville equation, $v(x)=u(x) \int^{x} \frac{d t}{p(t) u(t)^{2}}$ satisfies $\tau v=0$ whenever $\tau u=0$. Now fix $l=0$ and note $P_{0}(x)=1$. For $m=0$ we have $Q_{0}^{0}=\operatorname{arctanh}(x) \in L^{2}$ and so $\tau_{0}$ is l.c. at both endpoints. For $m>0$ we have $Q_{0}^{m}=(x \pm 1)^{-m / 2}(C+O(x \pm 1))$ which shows that it is not square integrable. Thus $\tau_{m}$ is l.c. for $m=0$ and l.p. for $m>0$ at both endpoints. In order to make sure that the eigenfunctions for $m=0$ are continuous (such that $\psi$ defined via (10.20) is continuous), we choose the boundary condition generated by $P_{0}(x)=1$ in this case:

$$
\begin{align*}
& A_{m} f=\tau_{m} f, \\
& \mathfrak{D}\left(A_{m}\right)=\left\{f \in L^{2}(-1,1) \mid\right.  \tag{10.35}\\
& f \in A C^{1}(-1,1), \tau_{m} f \in L^{2}(-1,1) \\
&\left.\lim _{x \rightarrow \pm 1}\left(1-x^{2}\right) f^{\prime}(x)=0 \text { if } m=0\right\}
\end{align*}
$$

Theorem 10.6. The operator $A_{m}$, $m \in \mathbb{N}_{0}$, defined via (10.35) is selfadjoint. Its spectrum is purely discrete, that is,

$$
\begin{equation*}
\sigma\left(A_{m}\right)=\sigma_{d}\left(A_{m}\right)=\left\{l(l+1) \mid l \in \mathbb{N}_{0}, l \geq m\right\} \tag{10.36}
\end{equation*}
$$

and the corresponding eigenfunctions

$$
\begin{equation*}
u_{l, m}(x)=\sqrt{\frac{2 l+1}{2} \frac{(l-m)!}{(l+m)!}} P_{l}^{m}(x), \quad l \in \mathbb{N}_{0}, l \geq m \tag{10.37}
\end{equation*}
$$

form an orthonormal basis for $L^{2}(-1,1)$.

Proof. By Theorem 9.6, $A_{m}$ is self-adjoint. Moreover, $P_{l}^{m}$ is an eigenfunction corresponding to the eigenvalue $l(l+1)$ and it suffices to show that the $P_{l}^{m}$ form a basis. To prove this, it suffices to show that the functions $P_{l}^{m}(x)$ are dense. Since $\left(1-x^{2}\right)>0$ for $x \in(-1,1)$, it suffices to show that the functions $\left(1-x^{2}\right)^{-m / 2} P_{l}^{m}(x)$ are dense. But the span of these functions contains every polynomial. Every continuous function can be approximated by polynomials (in the sup norm, Theorem 0.15 , and hence in the $L^{2}$ norm) and since the continuous functions are dense, so are the polynomials.

For the normalization of the eigenfunctions see Problem 10.7, respectively, [1, (8.14.13)].

Returning to our original setting, we conclude that the

$$
\begin{equation*}
\Theta_{l}^{m}(\theta)=\sqrt{\frac{2 l+1}{2} \frac{(l+m)!}{(l-m)!}} P_{l}^{m}(\cos (\theta)), \quad|m| \leq l \tag{10.38}
\end{equation*}
$$

form an orthonormal basis for $L^{2}((0, \pi), \sin (\theta) d \theta)$ for any fixed $m \in \mathbb{N}_{0}$.
Theorem 10.7. The operator $L^{2}$ on $L^{2}((0, \pi), \sin (\theta) d \theta) \otimes L^{2}((0,2 \pi))$ has a purely discrete spectrum given

$$
\begin{equation*}
\sigma\left(L^{2}\right)=\left\{l(l+1) \mid l \in \mathbb{N}_{0}\right\} . \tag{10.39}
\end{equation*}
$$

The spherical harmonics

$$
\begin{equation*}
Y_{l}^{m}(\theta, \varphi)=\Theta_{l}^{m}(\theta) \Phi_{m}(\varphi)=\sqrt{\frac{2 l+1}{4 \pi} \frac{(l-m)!}{(l+m)!}} P_{l}^{m}(\cos (\theta)) \mathrm{e}^{\mathrm{i} m \varphi}, \quad|m| \leq l, \tag{10.40}
\end{equation*}
$$

form an orthonormal basis and satisfy $L^{2} Y_{l}^{m}=l(l+1) Y_{l}^{m}$ and $L_{3} Y_{l}^{m}=$ $m Y_{l}^{m}$.

Proof. Everything follows from our construction, if we can show that the $Y_{l}^{m}$ form a basis. But this follows as in the proof of Lemma 1.10.

Note that transforming the $Y_{l}^{m}$ back to cartesian coordinates gives

$$
\begin{equation*}
Y_{l}^{ \pm m}(x)=(-1)^{m} \sqrt{\frac{2 l+1}{4 \pi} \frac{(l-|m|)!}{(l+|m|)!}} \tilde{P}_{l}^{m}\left(\frac{x_{3}}{r}\right)\left(\frac{x_{1} \pm \mathrm{i} x_{2}}{r}\right)^{m}, \quad r=|x|, \tag{10.41}
\end{equation*}
$$

where $\tilde{P}_{l}^{m}$ is a polynomial of degree $l-m$ given by

$$
\begin{equation*}
\tilde{P}_{l}^{m}(x)=\left(1-x^{2}\right)^{-m / 2} P_{l}^{m}(x)=\frac{d^{l+m}}{d x^{l+m}}\left(1-x^{2}\right)^{l} . \tag{10.42}
\end{equation*}
$$

In particular, the $Y_{l}^{m}$ are smooth away from the origin and by construction they satisfy

$$
\begin{equation*}
-\Delta Y_{l}^{m}=\frac{l(l+1)}{r^{2}} Y_{l}^{m} . \tag{10.43}
\end{equation*}
$$

Problem 10.2. Show that the associated Legendre functions satisfy the differential equation (10.30). (Hint: Start with the Legendre polynomials (10.32) which correspond to $m=0$. Set $v(x)=\left(x^{2}-1\right)^{l}$ and observe $\left(x^{2}-1\right) v^{\prime}(x)=2 \operatorname{lx} v(x)$. Then differentiate this identity $l+1$ times using Leibniz's rule. For the case of the associated Legendre functions, substitute $v(x)=\left(1-x^{2}\right)^{m / 2} u(x)$ in (10.30) and differentiate the resulting equation once.)

Problem 10.3. Show (10.33). (Hint: Write $\left(x^{2}-1\right)^{l}=(x-1)^{l}(x+1)^{l}$ and use Leibniz's rule.)

Problem 10.4 (Orthogonal polynomials). Suppose the monic polynomials $P_{j}(x)=x^{j}+\beta_{j} x^{j-1}+\ldots$ are orthogonal with respect to the weight function $w(x)$ :

$$
\int_{a}^{b} P_{i}(x) P_{j}(x) w(x) d x= \begin{cases}\alpha_{j}^{2}, & i=j \\ 0, & \text { otherwise } .\end{cases}
$$

Note that they are uniquely determined by the Gram-Schmidt procedure. Let $\bar{P}_{j}(x)=\alpha_{j}^{-1} P(x)$ and show that they satisfy the three term recurrence relation

$$
a_{j} \bar{P}_{j+1}(x)+b_{j} \bar{P}_{j}(x)+a_{j-1} \bar{P}_{j-1}(x)=x \bar{P}_{j}(x),
$$

where

$$
a_{j}=\int_{a}^{b} x \bar{P}_{j+1}(x) \bar{P}_{j}(x) w(x) d x, \quad b_{j}=\int_{a}^{b} x \bar{P}_{j}(x)^{2} w(x) d x .
$$

Moreover, show

$$
a_{j}=\frac{\alpha_{j+1}}{\alpha_{j}}, \quad b_{j}=\beta_{j}-\beta_{j+1} .
$$

(Note that $w(x) d x$ could be replaced by a measure $d \mu(x)$.)
Problem 10.5. Consider the orthogonal polynomials with respect to the weight function $w(x)$ as in the previous problem. Suppose $|w(x)| \leq C \mathrm{e}^{-k|x|}$ for some $C, k>0$. Show that the orthogonal polynomials are dense in $L^{2}(\mathbb{R}, w(x) d x)$. (Hint: It suffices to show that $\int f(x) x^{j} w(x) d x=0$ for all $j \in \mathbb{N}_{0}$ implies $f=0$. Consider the Fourier transform of $f(x) w(x)$ and note that it has an analytic extension by Problem 7.11. Hence this Fourier transform will be zero if, e.g., all derivatives at $p=0$ are zero (cf. Problem 7.3).)

Problem 10.6. Show

$$
P_{l}(x)=\sum_{k=0}^{\lfloor l / 2\rfloor} \frac{(-1)^{k}(2 l-2 k)!}{2^{l} k!(l-k)!(l-2 k)!} x^{l-2 k} .
$$

Moreover, by Problem 10.4 there is a recurrence relation of the form $P_{l+1}(x)=$ $\left(\tilde{a}_{l}+\tilde{b}_{l} x\right) P_{l}(x)+\tilde{c}_{l} P_{l-1}(x)$. Find the coefficients by comparing the highest powers in $x$ and conclude

$$
(l+1) P_{l+1}(x)=(2 l+1) x P_{l}(x)-l P_{l-1} .
$$

Use this to prove

$$
\int_{-1}^{1} P_{l}(x)^{2} d x=\frac{2}{2 l+1} .
$$

Problem 10.7. Prove

$$
\int_{-1}^{1} P_{l}^{m}(x)^{2} d x=\frac{2}{2 l+1} \frac{(l+m)!}{(l-m)!} .
$$

(Hint: Use (10.33) to compute $\int_{-1}^{1} P_{l}^{m}(x) P_{l}^{-m}(x) d x$ by integrating by parts until you can use the case $m=0$ from the previous problem.)

### 10.4. The eigenvalues of the hydrogen atom

Now we want to use the considerations from the previous section to decompose the Hamiltonian of the hydrogen atom. In fact, we can even admit any spherically symmetric potential $V(x)=V(|x|)$ with

$$
\begin{equation*}
V(r) \in L_{\infty}^{\infty}(\mathbb{R})+L^{2}\left((0, \infty), r^{2} d r\right) \tag{10.44}
\end{equation*}
$$

such that Theorem 10.2 holds.
The important observation is that the spaces

$$
\begin{equation*}
\mathfrak{H}_{l, m}=\left\{\psi(x)=R(r) Y_{l}^{m}(\theta, \varphi) \mid R(r) \in L^{2}\left((0, \infty), r^{2} d r\right)\right\} \tag{10.45}
\end{equation*}
$$

with corresponding projectors

$$
\begin{equation*}
P_{l}^{m} \psi(r, \theta, \varphi)=\left(\int_{0}^{2 \pi} \int_{0}^{\pi} \psi\left(r, \theta^{\prime}, \varphi^{\prime}\right) Y_{l}^{m}\left(\theta^{\prime}, \varphi^{\prime}\right) \sin \left(\theta^{\prime}\right) d \theta^{\prime} d \varphi^{\prime}\right) Y_{l}^{m}(\theta, \varphi) \tag{10.46}
\end{equation*}
$$

reduce our operator $H=H_{0}+V$. By Lemma 2.24 it suffices to check this for $H$ restricted to $C_{c}^{\infty}\left(\mathbb{R}^{3}\right)$, which is straightforward. Hence, again by Lemma 2.24,

$$
\begin{equation*}
H=H_{0}+V=\bigoplus_{l, m} \tilde{H}_{l}, \tag{10.47}
\end{equation*}
$$

where

$$
\begin{align*}
\tilde{H}_{l} R(r) & =\tilde{\tau}_{l} R(r), \quad \tilde{\tau}_{l}=-\frac{1}{r^{2}} \frac{d}{d r} r^{2} \frac{d}{d r}+\frac{l(l+1)}{r^{2}}+V(r), \\
\mathfrak{D}\left(H_{l}\right) & \subseteq L^{2}\left((0, \infty), r^{2} d r\right) \tag{10.48}
\end{align*}
$$

Using the unitary transformation

$$
\begin{equation*}
L^{2}\left((0, \infty), r^{2} d r\right) \rightarrow L^{2}((0, \infty)), \quad R(r) \mapsto u(r)=r R(r), \tag{10.49}
\end{equation*}
$$

our operator transforms to

$$
\begin{align*}
A_{l} f & =\tau_{l} f, \quad \tau_{l}=-\frac{d^{2}}{d r^{2}}+\frac{l(l+1)}{r^{2}}+V(r), \\
\mathfrak{D}\left(A_{l}\right) & =P_{l}^{m} \mathfrak{D}(H) \subseteq L^{2}((0, \infty)) . \tag{10.50}
\end{align*}
$$

It remains to investigate this operator (that its domain is indeed independent of $m$ follows from the next theorem).
Theorem 10.8. The domain of the operator $A_{l}$ is given by

$$
\mathfrak{D}\left(A_{l}\right)=\left\{f \in L^{2}(I) \left\lvert\, \begin{array}{ll}
f, f^{\prime} \in A C(I), \tau f \in L^{2}(I),  \tag{10.51}\\
& \left.\lim _{r \rightarrow 0}\left(f(r)-r f^{\prime}(r)\right)=0 \text { if } l=0\right\},
\end{array}\right.\right.
$$

where $I=(0, \infty)$. Moreover,

$$
\begin{equation*}
\sigma_{e s s}\left(A_{l}\right)=\sigma_{a c}\left(A_{l}\right)=[0, \infty), \quad \sigma_{s c}\left(A_{l}\right)=\emptyset, \quad \sigma_{p} \subset(-\infty, 0] . \tag{10.52}
\end{equation*}
$$

Proof. By construction of $A_{l}$ we know that it is self-adjoint and satisfies $\sigma_{\text {ess }}\left(A_{l}\right) \subseteq[0, \infty)$ (Problem 10.8). By Lemma 9.37 we have $(0, \infty) \subseteq N_{\infty}\left(\tau_{l}\right)$ and hence Theorem 9.31 implies $\sigma_{a c}\left(A_{l}\right)=[0, \infty), \sigma_{s c}\left(A_{l}\right)=\emptyset$, and $\sigma_{p} \subset$ $(-\infty, 0]$. So it remains to compute the domain. We know at least $\mathfrak{D}\left(A_{l}\right) \subseteq$ $\mathfrak{D}(\tau)$ and since $\mathfrak{D}(H)=\mathfrak{D}\left(H_{0}\right)$, it suffices to consider the case $V=0$. In this case the solutions of $-u^{\prime \prime}(r)+\frac{l(l+1)}{r^{2}} u(r)=0$ are given by $u(r)=\alpha r^{l+1}+\beta r^{-l}$. Thus we are in the l.p. case at $\infty$ for any $l \in \mathbb{N}_{0}$. However, at 0 we are in the l.p. case only if $l>0$; that is, we need an additional boundary condition at 0 if $l=0$. Since we need $R(r)=\frac{u(r)}{r}$ to be bounded (such that (10.20) is in the domain of $H_{0}$, that is, continuous), we have to take the boundary condition generated by $u(r)=r$.

Finally let us turn to some explicit choices for $V$, where the corresponding differential equation can be explicitly solved. The simplest case is $V=0$. In this case the solutions of

$$
\begin{equation*}
-u^{\prime \prime}(r)+\frac{l(l+1)}{r^{2}} u(r)=z u(r) \tag{10.53}
\end{equation*}
$$

are given by

$$
\begin{equation*}
u(r)=\alpha z^{-l / 2} r j_{l}(\sqrt{z} r)+\beta z^{(l+1) / 2} r y_{l}(\sqrt{z} r), \tag{10.54}
\end{equation*}
$$

where $j_{l}(r)$ and $y_{l}(r)$ are the spherical Bessel, respectively, spherical Neumann, functions

$$
\begin{align*}
j_{l}(r) & =\sqrt{\frac{\pi}{2 r}} J_{l+1 / 2}(r)=(-r)^{l}\left(\frac{1}{r} \frac{d}{d r}\right)^{l} \frac{\sin (r)}{r} \\
y_{l}(r) & =\sqrt{\frac{\pi}{2 r}} Y_{l+1 / 2}(r)=-(-r)^{l}\left(\frac{1}{r} \frac{d}{d r}\right)^{l} \frac{\cos (r)}{r} . \tag{10.55}
\end{align*}
$$

Note that $z^{-l / 2} r j_{l}(\sqrt{z} r)$ and $z^{(l+1) / 2} r y_{l}(\sqrt{z} r)$ are entire as functions of $z$ and their Wronskian is given by $W\left(z^{-l / 2} r j_{l}(\sqrt{z} r), z^{(l+1) / 2} r y_{l}(\sqrt{z} r)\right)=1$. See [1, Sects. 10.1 and 10.3]. In particular,

$$
\begin{align*}
& u_{a}(z, r)=\frac{r}{z^{l / 2}} j_{l}(\sqrt{z} r)=\frac{2^{l} l!}{(2 l+1)!} r^{l+1}\left(1+O\left(r^{2}\right)\right), \\
& u_{b}(z, r)=\sqrt{-z} r\left(j_{l}(\mathrm{i} \sqrt{-z} r)+\mathrm{i} y_{l}(\mathrm{i} \sqrt{-z} r)\right)=\mathrm{e}^{-\sqrt{-z} r+\mathrm{i} l \pi / 2}\left(1+O\left(\frac{1}{r}\right)\right) \tag{10.56}
\end{align*}
$$

are the functions which are square integrable and satisfy the boundary condition (if any) near $a=0$ and $b=\infty$, respectively.

The second case is that of our Coulomb potential

$$
\begin{equation*}
V(r)=-\frac{\gamma}{r}, \quad \gamma>0 \tag{10.57}
\end{equation*}
$$

where we will try to compute the eigenvalues plus corresponding eigenfunctions. It turns out that they can be expressed in terms of the Laguerre polynomials ([1, (22.2.13)])

$$
\begin{equation*}
L_{j}(r)=\frac{\mathrm{e}^{r}}{j!} \frac{d^{j}}{d r^{j}} \mathrm{e}^{-r} r^{j} \tag{10.58}
\end{equation*}
$$

and the generalized Laguerre polynomials ([1, (22.2.12)])

$$
\begin{equation*}
L_{j}^{(k)}(r)=(-1)^{k} \frac{d^{k}}{d r^{k}} L_{j+k}(r) . \tag{10.59}
\end{equation*}
$$

Note that the $L_{j}^{(k)}(r)$ are polynomials of degree $j-k$ which are explicitly given by

$$
\begin{equation*}
L_{j}^{(k)}(r)=\sum_{i=0}^{j}(-1)^{i}\binom{j+k}{j-i} \frac{r^{i}}{i!} \tag{10.60}
\end{equation*}
$$

and satisfy the differential equation (Problem 10.9)

$$
\begin{equation*}
r y^{\prime \prime}(r)+(k+1-r) y^{\prime}(r)+j y(r)=0 . \tag{10.61}
\end{equation*}
$$

Moreover, they are orthogonal in the Hilbert space $L^{2}\left((0, \infty), r^{k} \mathrm{e}^{-r} d r\right)$ (Problem 10.10):

$$
\int_{0}^{\infty} L_{j}^{(k)}(r) L_{j}^{(k)}(r) r^{k} \mathrm{e}^{-r} d r= \begin{cases}\frac{(j+k)!}{j!}, & i=j  \tag{10.62}\\ 0, & \text { otherwise }\end{cases}
$$

Theorem 10.9. The eigenvalues of $H^{(1)}$ are explicitly given by

$$
\begin{equation*}
E_{n}=-\left(\frac{\gamma}{2(n+1)}\right)^{2}, \quad n \in \mathbb{N}_{0} \tag{10.63}
\end{equation*}
$$

An orthonormal basis for the corresponding eigenspace is given by the $(n+1)^{2}$ functions

$$
\begin{equation*}
\psi_{n, l, m}(x)=R_{n, l}(r) Y_{l}^{m}(x), \quad|m| \leq l \leq n \tag{10.64}
\end{equation*}
$$

where

$$
\begin{equation*}
R_{n, l}(r)=\sqrt{\frac{\gamma^{3}(n-l)!}{2(n+1)^{4}(n+l+1)!}}\left(\frac{\gamma r}{n+1}\right)^{l} \mathrm{e}^{-\frac{\gamma r}{2(n+1)}} L_{n-l}^{(2 l+1)}\left(\frac{\gamma r}{n+1}\right) \tag{10.65}
\end{equation*}
$$

In particular, the lowest eigenvalue $E_{0}=-\frac{\gamma^{2}}{4}$ is simple and the corresponding eigenfunction $\psi_{000}(x)=\sqrt{\frac{\gamma^{3}}{2}} \mathrm{e}^{-\gamma r / 2}$ is positive.

Proof. Since all eigenvalues are negative, we need to look at the equation

$$
-u^{\prime \prime}(r)+\left(\frac{l(l+1)}{r^{2}}-\frac{\gamma}{r}\right) u(r)=\lambda u(r)
$$

for $\lambda<0$. Introducing new variables $x=2 \sqrt{-\lambda} r$ and $v(x)=\frac{\mathrm{e}^{x / 2}}{x^{l+1}} u\left(\frac{x}{2 \sqrt{-\lambda}}\right)$, this equation transforms into Kummer's equation

$$
x v^{\prime \prime}(x)+(k+1-x) v^{\prime}(x)+j v(x)=0, \quad k=2 l+1, j=\frac{\gamma}{2 \sqrt{-\lambda}}-(l+1)
$$

Now let us search for a solution which can be expanded into a convergent power series

$$
\begin{equation*}
v(x)=\sum_{i=0}^{\infty} v_{i} x^{i}, \quad v_{0}=1 \tag{10.66}
\end{equation*}
$$

The corresponding $u(r)$ is square integrable near 0 and satisfies the boundary condition (if any). Thus we need to find those values of $\lambda$ for which it is square integrable near $+\infty$.

Substituting the ansatz (10.66) into our differential equation and comparing powers of $x$ gives the following recursion for the coefficients

$$
v_{i+1}=\frac{(i-j)}{(i+1)(i+k+1)} v_{i}
$$

and thus

$$
v_{i}=\frac{1}{i!} \prod_{\ell=0}^{i-1} \frac{\ell-j}{\ell+k+1}
$$

Now there are two cases to distinguish. If $j \in \mathbb{N}_{0}$, then $v_{i}=0$ for $i>j$ and $v(x)$ is a polynomial; namely

$$
v(x)=\binom{j+k}{j}^{-1} L_{j}^{(k)}(x)
$$

In this case $u(r)$ is square integrable and hence an eigenfunction corresponding to the eigenvalue $\lambda_{j}=-\left(\frac{\gamma}{2(n+1)}\right)^{2}, n=j+l$. This proves the formula for $R_{n, l}(r)$ except for the normalization which follows from (Problem 10.11)

$$
\begin{equation*}
\int_{0}^{\infty} L_{j}^{(k)}(r)^{2} r^{k+1} \mathrm{e}^{-r} d r=\frac{(j+k)!}{j!}(2 j+k+1) . \tag{10.67}
\end{equation*}
$$

It remains to show that we have found all eigenfunctions, that is, that there are no other square integrable solutions. Otherwise, if $j \notin \mathbb{N}$, we have $\frac{v_{i+1}}{v_{i}} \geq \frac{(1-\varepsilon)}{i+1}$ for $i$ sufficiently large. Hence by adding a polynomial to $v(x)$ (and perhaps flipping its sign), we can get a function $\tilde{v}(x)$ such that $\tilde{v}_{i} \geq$ $\frac{(1-\varepsilon)^{i}}{i!}$ for all $i$. But then $\tilde{v}(x) \geq \exp ((1-\varepsilon) x)$ and thus the corresponding $u(r)$ is not square integrable near $+\infty$.

Finally, let us also look at an alternative algebraic approach for computing the eigenvalues and eigenfunctions of $A_{l}$ based on the commutation methods from Section 8.4. We begin by introducing

$$
\begin{align*}
Q_{l} f & =-\frac{d}{d r}+\frac{l+1}{r}-\frac{\gamma}{2(l+1)}, \\
\mathfrak{D}\left(Q_{l}\right) & =\left\{f \in L^{2}((0, \infty)) \mid f \in A C((0, \infty)), Q_{l} f \in L^{2}((0, \infty))\right\} . \tag{10.68}
\end{align*}
$$

Then (Problem 9.3) $Q_{l}$ is closed and its adjoint is given by

$$
\begin{align*}
Q_{l}^{*} f= & \frac{d}{d r}+\frac{l+1}{r}-\frac{\gamma}{2(l+1)}, \\
\mathfrak{D}\left(Q_{l}^{*}\right)=\left\{f \in L^{2}((0, \infty)) \mid\right. & \mid f \in A C((0, \infty)), Q_{l}^{*} f \in L^{2}((0, \infty)),  \tag{10.69}\\
& \left.\lim _{x \rightarrow 0, \infty} f(x) g(x)=0, \forall g \in \mathfrak{D}\left(Q_{l}\right)\right\} .
\end{align*}
$$

It is straightforward to check

$$
\begin{equation*}
\operatorname{Ker}\left(Q_{l}\right)=\operatorname{span}\left\{u_{l, 0}\right\}, \quad \operatorname{Ker}\left(Q_{l}^{*}\right)=\{0\}, \tag{10.70}
\end{equation*}
$$

where

$$
\begin{equation*}
u_{l, 0}(r)=\frac{1}{\sqrt{(2 l+2)!}}\left(\frac{\gamma}{l+1}\right)^{(l+1)+1 / 2} r^{l+1} \mathrm{e}^{-\frac{\gamma}{2(l+1)} r} \tag{10.71}
\end{equation*}
$$

is normalized.
Theorem 10.10. The radial Schrödinger operator $A_{l}$ satisfies

$$
\begin{equation*}
A_{l}=Q_{l}^{*} Q_{l}-c_{l}^{2}, \quad A_{l+1}=Q_{l} Q_{l}^{*}-c_{l}^{2}, \tag{10.72}
\end{equation*}
$$

where

$$
\begin{equation*}
c_{l}=\frac{\gamma}{2(l+1)} . \tag{10.73}
\end{equation*}
$$

Proof. Equality is easy to check for $f \in A C^{2}$ with compact support. Hence $Q_{l}^{*} Q_{l}-c_{l}^{2}$ is a self-adjoint extension of $\tau_{l}$ restricted to this set. If $l>0$, there is only one self-adjoint extension and equality follows. If $l=0$, we know $u_{0,0} \in \mathfrak{D}\left(Q_{l}^{*} Q_{l}\right)$ and since $A_{l}$ is the only self-adjoint extension with $u_{0,0} \in \mathfrak{D}\left(A_{l}\right)$, equality follows in this case as well.

Hence, as a consequence of Theorem 8.6 we see $\sigma\left(A_{l}\right)=\sigma\left(A_{l+1}\right) \cup\left\{-c_{l}^{2}\right\}$, or, equivalently,

$$
\begin{equation*}
\sigma_{p}\left(A_{l}\right)=\left\{-c_{j}^{2} \mid j \geq l\right\} \tag{10.74}
\end{equation*}
$$

if we use that $\sigma_{p}\left(A_{l}\right) \subset(-\infty, 0)$, which already follows from the virial theorem. Moreover, using $Q_{l}$, we can turn any eigenfunction of $H_{l}$ into one of $H_{l+1}$. However, we only know the lowest eigenfunction $u_{l, 0}$, which is mapped to 0 by $Q_{l}$. On the other hand, we can also use $Q_{l}^{*}$ to turn an eigenfunction of $H_{l+1}$ into one of $H_{l}$. Hence $Q_{l}^{*} u_{l+1,0}$ will give the second eigenfunction of $H_{l}$. Proceeding inductively, the normalized eigenfunction of $H_{l}$ corresponding to the eigenvalue $-c_{l+j}^{2}$ is given by

$$
\begin{equation*}
u_{l, j}=\left(\prod_{k=0}^{j-1}\left(c_{l+j}-c_{l+k}\right)\right)^{-1} Q_{l}^{*} Q_{l+1}^{*} \cdots Q_{l+j-1}^{*} u_{l+j, 0} \tag{10.75}
\end{equation*}
$$

The connection with Theorem 10.9 is given by

$$
\begin{equation*}
R_{n, l}(r)=\frac{1}{r} u_{l, n-l}(r) . \tag{10.76}
\end{equation*}
$$

Problem 10.8. Let $A=\bigoplus_{n} A_{n}$. Then $\bigcup_{n} \sigma_{\text {ess }}\left(A_{n}\right) \subseteq \sigma_{\text {ess }}(A)$.
Problem 10.9. Show that the generalized Laguerre polynomials satisfy the differential equation (10.61). (Hint: Start with the Laguerre polynomials (10.58) which correspond to $k=0$. Set $v(r)=r^{j} \mathrm{e}^{-r}$ and observe $r v^{\prime}(r)=$ $(j-r) v(r)$. Then differentiate this identity $j+1$ times using Leibniz's rule. For the case of the generalized Laguerre polynomials, start with the differential equation for $L_{j+k}(r)$ and differentiate $k$ times.)

Problem 10.10. Show that the differential equation (10.58) can be rewritten in Sturm-Liouville form as

$$
-r^{-k} \mathrm{e}^{r} \frac{d}{d r} r^{k+1} \mathrm{e}^{-r} \frac{d}{d r} u=j u .
$$

We have found one entire solution in the proof of Theorem 10.9. Show that any linearly independent solution behaves like $\log (r)$ if $k=0$, respectively, like $r^{-k}$ otherwise. Show that it is l.c. at the endpoint $r=0$ if $k=0$ and l.p. otherwise.

Let $\mathfrak{H}=L^{2}\left((0, \infty), r^{k} \mathrm{e}^{-r} d r\right)$. The operator

$$
\begin{aligned}
& A_{k} f= \tau f=-r^{-k} \mathrm{e}^{r} \frac{d}{d r} r^{k+1} \mathrm{e}^{-r} \frac{d}{d r} f, \\
& \mathfrak{D}\left(A_{k}\right)=\left\{f \in \mathfrak{H} \mid \quad f \in A C^{1}(0, \infty), \tau_{k} f \in \mathfrak{H},\right. \\
&\left.\lim _{r \rightarrow 0} r f^{\prime}(r)=0 \text { if } k=0\right\}
\end{aligned}
$$

for $k \in \mathbb{N}_{0}$ is self-adjoint. Its spectrum is purely discrete, that is,

$$
\begin{equation*}
\sigma\left(A_{k}\right)=\sigma_{d}\left(A_{k}\right)=\mathbb{N}_{0}, \tag{10.77}
\end{equation*}
$$

and the corresponding eigenfunctions

$$
\begin{equation*}
L_{j}^{(k)}(r), \quad j \in \mathbb{N}_{0} \tag{10.78}
\end{equation*}
$$

form an orthogonal base for $\mathfrak{H}$. (Hint: Compare the argument for the associated Legendre equation and Problem 10.5.)

Problem 10.11. By Problem 10.4 there is a recurrence relation of the form $L_{j+1}^{(k)}(r)=\left(\tilde{a}_{j}+\tilde{b}_{j} r\right) L_{j}^{(k)}(r)+\tilde{c}_{j} L_{j-1}^{(k)}(r)$. Find the coefficients by comparing the highest powers in $r$ and conclude

$$
L_{j+1}^{(k)}(r)=\frac{1}{1+j}\left((2 j+k+1-r) L_{j}^{(k)}(r)-(j+k) L_{j-1}^{(k)}(r)\right) .
$$

Use this to prove (10.62) and (10.67).

### 10.5. Nondegeneracy of the ground state

The lowest eigenvalue (below the essential spectrum) of a Schrödinger operator is called the ground state. Since the laws of physics state that a quantum system will transfer energy to its surroundings (e.g., an atom emits radiation) until it eventually reaches its ground state, this state is in some sense the most important state. We have seen that the hydrogen atom has a nondegenerate (simple) ground state with a corresponding positive eigenfunction. In particular, the hydrogen atom is stable in the sense that there is a lowest possible energy. This is quite surprising since the corresponding classical mechanical system is not - the electron could fall into the nucleus!

Our aim in this section is to show that the ground state is simple with a corresponding positive eigenfunction. Note that it suffices to show that any ground state eigenfunction is positive since nondegeneracy then follows for free: two positive functions cannot be orthogonal.

To set the stage, let us introduce some notation. Let $\mathfrak{H}=L^{2}\left(\mathbb{R}^{n}\right)$. We call $f \in L^{2}\left(\mathbb{R}^{n}\right)$ positive if $f \geq 0$ a.e. and $f \not \equiv 0$. We call $f$ strictly positive if $f>0$ a.e. A bounded operator $A$ is called positivity preserving if $f \geq 0$ implies $A f \geq 0$ and positivity improving if $f \geq 0$ implies $A f>0$. Clearly $A$ is positivity preserving (improving) if and only if $\langle f, A g\rangle \geq 0$ $(>0)$ for $f, g \geq 0$.

Example. Multiplication by a positive function is positivity preserving (but not improving). Convolution with a strictly positive function is positivity improving.

We first show that positivity improving operators have positive eigenfunctions.

Theorem 10.11. Suppose $A \in \mathfrak{L}\left(L^{2}\left(\mathbb{R}^{n}\right)\right)$ is a self-adjoint, positivity improving and real (i.e., it maps real functions to real functions) operator. If $\|A\|$ is an eigenvalue, then it is simple and the corresponding eigenfunction is strictly positive.

Proof. Let $\psi$ be an eigenfunction. It is no restriction to assume that $\psi$ is real (since $A$ is real, both real and imaginary part of $\psi$ are eigenfunctions as well). We assume $\|\psi\|=1$ and denote by $\psi_{ \pm}=\frac{f \pm \| f \mid}{2}$ the positive and negative parts of $\psi$. Then by $|A \psi|=\left|A \psi_{+}-A \psi_{-}\right| \leq A \psi_{+}+A \psi_{-}=A|\psi|$ we have

$$
\|A\|=\langle\psi, A \psi\rangle \leq\langle | \psi|,|A \psi|\rangle \leq\langle | \psi|, A| \psi| \rangle \leq\|A\| ;
$$

that is, $\langle\psi, A \psi\rangle=\langle | \psi|, A| \psi| \rangle$ and thus

$$
\left\langle\psi_{+}, A \psi_{-}\right\rangle=\frac{1}{4}(\langle | \psi|, A| \psi| \rangle-\langle\psi, A \psi\rangle)=0 .
$$

Consequently $\psi_{-}=0$ or $\psi_{+}=0$ since otherwise $A \psi_{-}>0$ and hence also $\left\langle\psi_{+}, A \psi_{-}\right\rangle>0$. Without restriction $\psi=\psi_{+} \geq 0$ and since $A$ is positivity increasing, we even have $\psi=\|A\|^{-1} A \psi>0$.

So we need a positivity improving operator. By (7.38) and (7.39) both $\mathrm{e}^{-t H_{0}}, t>0$, and $R_{\lambda}\left(H_{0}\right), \lambda<0$, are since they are given by convolution with a strictly positive function. Our hope is that this property carries over to $H=H_{0}+V$.

Theorem 10.12. Suppose $H=H_{0}+V$ is self-adjoint and bounded from below with $C_{c}^{\infty}\left(\mathbb{R}^{n}\right)$ as a core. If $E_{0}=\min \sigma(H)$ is an eigenvalue, it is simple and the corresponding eigenfunction is strictly positive.

Proof. We first show that $\mathrm{e}^{-t H}, t>0$, is positivity preserving. If we set $V_{n}=V \chi_{\{x| | V(x) \mid \leq n\}}$, then $V_{n}$ is bounded and $H_{n}=H_{0}+V_{n}$ is positivity preserving by the Trotter product formula since both $\mathrm{e}^{-t H_{0}}$ and $\mathrm{e}^{-t V}$ are. Moreover, we have $H_{n} \psi \rightarrow H \psi$ for $\psi \in C_{c}^{\infty}\left(\mathbb{R}^{n}\right)$ (note that necessarily $\left.V \in L_{l o c}^{2}\right)$ and hence $H_{n} \xrightarrow{s r} H$ in the strong resolvent sense by Lemma 6.36. Hence $\mathrm{e}^{-t H_{n}} \xrightarrow{s} \mathrm{e}^{-t H}$ by Theorem 6.31, which shows that $\mathrm{e}^{-t H}$ is at least positivity preserving (since 0 cannot be an eigenvalue of $\mathrm{e}^{-t H}$, it cannot map a positive function to 0 ).

Next I claim that for $\psi$ positive the closed set

$$
N(\psi)=\left\{\varphi \in L^{2}\left(\mathbb{R}^{n}\right) \mid \varphi \geq 0,\left\langle\varphi, \mathrm{e}^{-s H} \psi\right\rangle=0 \forall s \geq 0\right\}
$$

is just $\{0\}$. If $\varphi \in N(\psi)$, we have by $\mathrm{e}^{-s H} \psi \geq 0$ that $\varphi \mathrm{e}^{-s H} \psi=0$. Hence $\mathrm{e}^{t V_{n}} \varphi \mathrm{e}^{-s H} \psi=0$; that is, $\mathrm{e}^{t V_{n}} \varphi \in N(\psi)$. In other words, both $\mathrm{e}^{t V_{n}}$ and $\mathrm{e}^{-t H}$ leave $N(\psi)$ invariant and invoking Trotter's formula again, the same is true for

$$
\mathrm{e}^{-t\left(H-V_{n}\right)}=\underset{k \rightarrow \infty}{\mathrm{~s}-\lim _{\infty}}\left(\mathrm{e}^{-\frac{t}{k} H} \mathrm{e}^{\frac{t}{k} V_{n}}\right)^{k} .
$$

Since $\mathrm{e}^{-t\left(H-V_{n}\right)} \xrightarrow{s} \mathrm{e}^{-t H_{0}}$, we finally obtain that $\mathrm{e}^{-t H_{0}}$ leaves $N(\psi)$ invariant, but this operator is positivity increasing and thus $N(\psi)=\{0\}$.

Now it remains to use (7.37), which shows

$$
\left\langle\varphi, R_{H}(\lambda) \psi\right\rangle=\int_{0}^{\infty} \mathrm{e}^{\lambda t}\left\langle\varphi, \mathrm{e}^{-t H} \psi\right\rangle d t>0, \quad \lambda<E_{0},
$$

for $\varphi, \psi$ positive. So $R_{H}(\lambda)$ is positivity increasing for $\lambda<E_{0}$.
If $\psi$ is an eigenfunction of $H$ corresponding to $E_{0}$, it is an eigenfunction of $R_{H}(\lambda)$ corresponding to $\frac{1}{E_{0}-\lambda}$ and the claim follows since $\left\|R_{H}(\lambda)\right\|=$ $\frac{1}{E_{0}-\lambda}$.

The assumptions are for example satisfied for the potentials $V$ considered in Theorem 10.2.

## Atomic Schrödinger operators

### 11.1. Self-adjointness

In this section we want to have a look at the Hamiltonian corresponding to more than one interacting particle. It is given by

$$
\begin{equation*}
H=-\sum_{j=1}^{N} \Delta_{j}+\sum_{j<k}^{N} V_{j, k}\left(x_{j}-x_{k}\right) . \tag{11.1}
\end{equation*}
$$

We first consider the case of two particles, which will give us a feeling for how the many particle case differs from the one particle case and how the difficulties can be overcome.

We denote the coordinates corresponding to the first particle by $x_{1}=$ $\left(x_{1,1}, x_{1,2}, x_{1,3}\right)$ and those corresponding to the second particle by $x_{2}=$ $\left(x_{2,1}, x_{2,2}, x_{2,3}\right)$. If we assume that the interaction is again of the Coulomb type, the Hamiltonian is given by

$$
\begin{equation*}
H=-\Delta_{1}-\Delta_{2}-\frac{\gamma}{\left|x_{1}-x_{2}\right|}, \quad \mathfrak{D}(H)=H^{2}\left(\mathbb{R}^{6}\right) \tag{11.2}
\end{equation*}
$$

Since Theorem 10.2 does not allow singularities for $n \geq 3$, it does not tell us whether $H$ is self-adjoint or not. Let

$$
\left(y_{1}, y_{2}\right)=\frac{1}{\sqrt{2}}\left(\begin{array}{cc}
\mathbb{I} & \mathbb{I}  \tag{11.3}\\
-\mathbb{I} & \mathbb{I}
\end{array}\right)\left(x_{1}, x_{2}\right) .
$$

Then $H$ reads in this new coordinate system as

$$
\begin{equation*}
H=\left(-\Delta_{1}\right)+\left(-\Delta_{2}-\frac{\gamma / \sqrt{2}}{\left|y_{2}\right|}\right) . \tag{11.4}
\end{equation*}
$$

In particular, it is the sum of a free particle plus a particle in an external Coulomb field. From a physics point of view, the first part corresponds to the center of mass motion and the second part to the relative motion.

Using that $\gamma /\left(\sqrt{2}\left|y_{2}\right|\right)$ has $\left(-\Delta_{2}\right)$-bound 0 in $L^{2}\left(\mathbb{R}^{3}\right)$, it is not hard to see that the same is true for the $\left(-\Delta_{1}-\Delta_{2}\right)$-bound in $L^{2}\left(\mathbb{R}^{6}\right)$ (details will follow in the next section). In particular, $H$ is self-adjoint and semi-bounded for any $\gamma \in \mathbb{R}$. Moreover, you might suspect that $\gamma /\left(\sqrt{2}\left|y_{2}\right|\right)$ is relatively compact with respect to $-\Delta_{1}-\Delta_{2}$ in $L^{2}\left(\mathbb{R}^{6}\right)$ since it is with respect to $-\Delta_{2}$ in $L^{2}\left(\mathbb{R}^{6}\right)$. However, this is not true! This is due to the fact that $\gamma /\left(\sqrt{2}\left|y_{2}\right|\right)$ does not vanish as $|y| \rightarrow \infty$.

Let us look at this problem from the physical view point. If $\lambda \in \sigma_{\text {ess }}(H)$, this means that the movement of the whole system is somehow unbounded. There are two possibilities for this.

First, both particles are far away from each other (such that we can neglect the interaction) and the energy corresponds to the sum of the kinetic energies of both particles. Since both can be arbitrarily small (but positive), we expect $[0, \infty) \subseteq \sigma_{\text {ess }}(H)$.

Secondly, both particles remain close to each other and move together. In the last set of coordinates this corresponds to a bound state of the second operator. Hence we expect $\left[\lambda_{0}, \infty\right) \subseteq \sigma_{\text {ess }}(H)$, where $\lambda_{0}=-\gamma^{2} / 8$ is the smallest eigenvalue of the second operator if the forces are attracting $(\gamma \geq 0)$ and $\lambda_{0}=0$ if they are repelling ( $\gamma \leq 0$ ).

It is not hard to translate this intuitive idea into a rigorous proof. Let $\psi_{1}\left(y_{1}\right)$ be a Weyl sequence corresponding to $\lambda \in[0, \infty)$ for $-\Delta_{1}$ and let $\psi_{2}\left(y_{2}\right)$ be a Weyl sequence corresponding to $\lambda_{0}$ for $-\Delta_{2}-\gamma /\left(\sqrt{2}\left|y_{2}\right|\right)$. Then, $\psi_{1}\left(y_{1}\right) \psi_{2}\left(y_{2}\right)$ is a Weyl sequence corresponding to $\lambda+\lambda_{0}$ for $H$ and thus $\left[\lambda_{0}, \infty\right) \subseteq \sigma_{\text {ess }}(H)$. Conversely, we have $-\Delta_{1} \geq 0$, respectively, $-\Delta_{2}-$ $\gamma /\left(\sqrt{2}\left|y_{2}\right|\right) \geq \lambda_{0}$, and hence $H \geq \lambda_{0}$. Thus we obtain

$$
\sigma(H)=\sigma_{\text {ess }}(H)=\left[\lambda_{0}, \infty\right), \quad \lambda_{0}= \begin{cases}-\gamma^{2} / 8, & \gamma \geq 0,  \tag{11.5}\\ 0, & \gamma \leq 0 .\end{cases}
$$

Clearly, the physically relevant information is the spectrum of the operator $-\Delta_{2}-\gamma /\left(\sqrt{2}\left|y_{2}\right|\right)$ which is hidden by the spectrum of $-\Delta_{1}$. Hence, in order to reveal the physics, one first has to remove the center of mass motion.

To avoid clumsy notation, we will restrict ourselves to the case of one atom with $N$ electrons whose nucleus is fixed at the origin. In particular, this implies that we do not have to deal with the center of mass motion
encountered in our example above. In this case the Hamiltonian is given by

$$
\begin{align*}
H^{(N)} & =-\sum_{j=1}^{N} \Delta_{j}-\sum_{j=1}^{N} V_{n e}\left(x_{j}\right)+\sum_{j=1}^{N} \sum_{j<k}^{N} V_{e e}\left(x_{j}-x_{k}\right), \\
\mathfrak{D}\left(H^{(N)}\right) & =H^{2}\left(\mathbb{R}^{3 N}\right), \tag{11.6}
\end{align*}
$$

where $V_{n e}$ describes the interaction of one electron with the nucleus and $V_{e e}$ describes the interaction of two electrons. Explicitly we have

$$
\begin{equation*}
V_{j}(x)=\frac{\gamma_{j}}{|x|}, \quad \gamma_{j}>0, j=n e, e e . \tag{11.7}
\end{equation*}
$$

We first need to establish the self-adjointness of $H^{(N)}=H_{0}+V^{(N)}$. This will follow from Kato's theorem.

Theorem 11.1 (Kato). Let $V_{k} \in L_{\infty}^{\infty}\left(\mathbb{R}^{d}\right)+L^{2}\left(\mathbb{R}^{d}\right)$, $d \leq 3$, be real-valued and let $V_{k}\left(y^{(k)}\right)$ be the multiplication operator in $L^{2}\left(\mathbb{R}^{n}\right), n=N d$, obtained by letting $y^{(k)}$ be the first d coordinates of a unitary transform of $\mathbb{R}^{n}$. Then $V_{k}$ is $H_{0}$ bounded with $H_{0}$-bound 0 . In particular,

$$
\begin{equation*}
H=H_{0}+\sum_{k} V_{k}\left(y^{(k)}\right), \quad \mathfrak{D}(H)=H^{2}\left(\mathbb{R}^{n}\right), \tag{11.8}
\end{equation*}
$$

is self-adjoint and $C_{0}^{\infty}\left(\mathbb{R}^{n}\right)$ is a core.
Proof. It suffices to consider one $k$. After a unitary transform of $\mathbb{R}^{n}$ we can assume $y^{(1)}=\left(x_{1}, \ldots, x_{d}\right)$ since such transformations leave both the scalar product of $L^{2}\left(\mathbb{R}^{n}\right)$ and $H_{0}$ invariant. Now let $\psi \in \mathcal{S}\left(\mathbb{R}^{n}\right)$. Then

$$
\left\|V_{k} \psi\right\|^{2} \leq a^{2} \int_{\mathbb{R}^{n}}\left|\Delta_{1} \psi(x)\right|^{2} d^{n} x+b^{2} \int_{\mathbb{R}^{n}}|\psi(x)|^{2} d^{n} x
$$

where $\Delta_{1}=\sum_{j=1}^{d} \partial^{2} / \partial^{2} x_{j}$, by our previous lemma. Hence we obtain

$$
\begin{aligned}
\left\|V_{k} \psi\right\|^{2} & \leq a^{2} \int_{\mathbb{R}^{n}}\left|\sum_{j=1}^{d} p_{j}^{2} \hat{\psi}(p)\right|^{2} d^{n} p+b^{2}\|\psi\|^{2} \\
& \leq a^{2} \int_{\mathbb{R}^{n}}\left|\sum_{j=1}^{n} p_{j}^{2} \hat{\psi}(p)\right|^{2} d^{n} p+b^{2}\|\psi\|^{2} \\
& =a^{2}\left\|H_{0} \psi\right\|^{2}+b^{2}\|\psi\|^{2},
\end{aligned}
$$

which implies that $V_{k}$ is relatively bounded with bound 0 . The rest follows from the Kato-Rellich theorem.

So $V^{(N)}$ is $H_{0}$ bounded with $H_{0}$-bound 0 and thus $H^{(N)}=H_{0}+V^{(N)}$ is self-adjoint on $\mathfrak{D}\left(H^{(N)}\right)=\mathfrak{D}\left(H_{0}\right)$.

### 11.2. The HVZ theorem

The considerations of the beginning of this section show that it is not so easy to determine the essential spectrum of $H^{(N)}$ since the potential does not decay in all directions as $|x| \rightarrow \infty$. However, there is still something we can do. Denote the infimum of the spectrum of $H^{(N)}$ by $\lambda^{N}$. Then, let us split the system into $H^{(N-1)}$ plus a single electron. If the single electron is far away from the remaining system such that there is little interaction, the energy should be the sum of the kinetic energy of the single electron and the energy of the remaining system. Hence, arguing as in the two electron example of the previous section, we expect

Theorem 11.2 (HVZ). Let $H^{(N)}$ be the self-adjoint operator given in (11.6). Then $H^{(N)}$ is bounded from below and

$$
\begin{equation*}
\sigma_{e s s}\left(H^{(N)}\right)=\left[\lambda^{N-1}, \infty\right), \tag{11.9}
\end{equation*}
$$

where $\lambda^{N-1}=\min \sigma\left(H^{(N-1)}\right)<0$.

In particular, the ionization energy (i.e., the energy needed to remove one electron from the atom in its ground state) of an atom with $N$ electrons is given by $\lambda^{N}-\lambda^{N-1}$.

Our goal for the rest of this section is to prove this result which is due to Zhislin, van Winter, and Hunziker and is known as the HVZ theorem. In fact there is a version which holds for general $N$-body systems. The proof is similar but involves some additional notation.

The idea of proof is the following. To prove $\left[\lambda^{N-1}, \infty\right) \subseteq \sigma_{\text {ess }}\left(H^{(N)}\right)$, we choose Weyl sequences for $H^{(N-1)}$ and $-\Delta_{N}$ and proceed according to our intuitive picture from above. To prove $\sigma_{\text {ess }}\left(H^{(N)}\right) \subseteq\left[\lambda^{N-1}, \infty\right)$, we will localize $H^{(N)}$ on sets where one electron is far away from the nucleus whenever some of the others are. On these sets, the interaction term between this electron and the nucleus is decaying and hence does not contribute to the essential spectrum. So it remain to estimate the infimum of the spectrum of a system where one electron does not interact with the nucleus. Since the interaction term with the other electrons is positive, we can finally estimate this infimum by the infimum of the case where one electron is completely decoupled from the rest.

We begin with the first inclusion. Let $\psi^{N-1}\left(x_{1}, \ldots, x_{N-1}\right) \in H^{2}\left(\mathbb{R}^{3(N-1)}\right)$ such that $\left\|\psi^{N-1}\right\|=1,\left\|\left(H^{(N-1)}-\lambda^{N-1}\right) \psi^{N-1}\right\| \leq \varepsilon$ and $\psi^{1} \in H^{2}\left(\mathbb{R}^{3}\right)$ such that $\left\|\psi^{1}\right\|=1,\left\|\left(-\Delta_{N}-\lambda\right) \psi^{1}\right\| \leq \varepsilon$ for some $\lambda \geq 0$. Now consider

$$
\begin{align*}
& \psi_{r}\left(x_{1}, \ldots, x_{N}\right)=\psi^{N-1}\left(x_{1}, \ldots, x_{N-1}\right) \psi_{r}^{1}\left(x_{N}\right), \psi_{r}^{1}\left(x_{N}\right)=\psi^{1}\left(x_{N}-r\right) \text {. Then } \\
& \qquad \begin{aligned}
\left\|\left(H^{(N)}-\lambda-\lambda^{N-1}\right) \psi_{r}\right\| \leq & \left\|\left(H^{(N-1)}-\lambda^{N-1}\right) \psi^{N-1}\right\|\left\|\psi_{r}^{1}\right\| \\
& +\left\|\psi^{N-1}\right\|\left\|\left(-\Delta_{N}-\lambda\right) \psi_{r}^{1}\right\| \\
& +\left\|\left(V_{N}-\sum_{j=1}^{N-1} V_{N, j}\right) \psi_{r}\right\|,
\end{aligned}
\end{align*}
$$

where $V_{N}=V_{n e}\left(x_{N}\right)$ and $V_{N, j}=V_{e e}\left(x_{N}-x_{j}\right)$. Using the fact that $\left(V_{N}-\sum_{j=1}^{N-1} V_{N, j}\right) \psi^{N-1} \in L^{2}\left(\mathbb{R}^{3 N}\right)$ and $\left|\psi_{r}^{1}\right| \rightarrow 0$ pointwise as $|r| \rightarrow \infty$ (by Lemma 10.1), the third term can be made smaller than $\varepsilon$ by choosing $|r|$ large (dominated convergence). In summary,

$$
\begin{equation*}
\left\|\left(H^{(N)}-\lambda-\lambda^{N-1}\right) \psi_{r}\right\| \leq 3 \varepsilon \tag{11.11}
\end{equation*}
$$

proving $\left[\lambda^{N-1}, \infty\right) \subseteq \sigma_{e s s}\left(H^{(N)}\right)$.
The second inclusion is more involved. We begin with a localization formula.

Lemma 11.3 (IMS localization formula). Suppose $\phi_{j} \in C^{\infty}\left(\mathbb{R}^{n}\right), 1 \leq j \leq$ $m$, is such that

$$
\begin{equation*}
\sum_{j=1}^{m} \phi_{j}(x)^{2}=1, \quad x \in \mathbb{R}^{n} \tag{11.12}
\end{equation*}
$$

Then

$$
\begin{equation*}
\Delta \psi=\sum_{j=1}^{m}\left(\phi_{j} \Delta\left(\phi_{j} \psi\right)+\left|\partial \phi_{j}\right|^{2} \psi\right), \quad \psi \in H^{2}\left(\mathbb{R}^{n}\right) . \tag{11.13}
\end{equation*}
$$

Proof. The proof follows from a straightforward computation using the identities $\sum_{j} \phi_{j} \partial_{k} \phi_{j}=0$ and $\sum_{j}\left(\left(\partial_{k} \phi_{j}\right)^{2}+\phi_{j} \partial_{k}^{2} \phi_{j}\right)=0$ which follow by differentiating (11.12).

Now we will choose $\phi_{j}, 1 \leq j \leq N$, in such a way that, for $x$ outside some ball, $x \in \operatorname{supp}\left(\phi_{j}\right)$ implies that the $j$ 'th particle is far away from the nucleus.

Lemma 11.4. Fix some $C \in\left(0, \frac{1}{\sqrt{N}}\right)$. There exist smooth functions $\phi_{j} \in$ $C^{\infty}\left(\mathbb{R}^{n},[0,1]\right), 1 \leq j \leq N$, such that (11.12) holds,

$$
\begin{equation*}
\operatorname{supp}\left(\phi_{j}\right) \cap\left\{x||x| \geq 1\} \subseteq\left\{x\left|\left|x_{j}\right| \geq C\right| x \mid\right\}\right. \tag{11.14}
\end{equation*}
$$

and $\left|\partial \phi_{j}(x)\right| \rightarrow 0$ as $|x| \rightarrow \infty$.
Proof. The open sets

$$
U_{j}=\left\{x \in S^{3 N-1}| | x_{j} \mid>C\right\}
$$

cover the unit sphere in $\mathbb{R}^{N}$; that is,

$$
\bigcup_{j=1}^{N} U_{j}=S^{3 N-1}
$$

By Lemma 0.13 there is a partition of unity $\tilde{\phi}_{j}(x)$ subordinate to this cover. Extend $\tilde{\phi}_{j}(x)$ to a smooth function from $\mathbb{R}^{3 N} \backslash\{0\}$ to $[0,1]$ by

$$
\tilde{\phi}_{j}(\lambda x)=\tilde{\phi}_{j}(x), \quad x \in S^{3 N-1}, \lambda>0,
$$

and pick a function $\tilde{\phi} \in C^{\infty}\left(\mathbb{R}^{3 N},[0,1]\right)$ with support inside the unit ball which is 1 in a neighborhood of the origin. Then the

$$
\phi_{j}=\frac{\tilde{\phi}+(1-\tilde{\phi}) \tilde{\phi}_{j}}{\sqrt{\sum_{\ell=1}^{N}\left(\tilde{\phi}+(1-\tilde{\phi}) \tilde{\phi}_{\ell}\right)^{2}}}
$$

are the desired functions. The gradient tends to zero since $\phi_{j}(\lambda x)=\phi_{j}(x)$ for $\lambda \geq 1$ and $|x| \geq 1$ which implies $\left(\partial \phi_{j}\right)(\lambda x)=\lambda^{-1}\left(\partial \phi_{j}\right)(x)$.

By our localization formula we have

$$
\begin{align*}
& H^{(N)}=\sum_{j=1}^{N} \phi_{j} H^{(N, j)} \phi_{j}+P-K, \\
& K=\sum_{j=1}^{N}\left(\phi_{j}^{2} V_{j}+\left|\partial \phi_{j}\right|^{2}\right), \quad P=\sum_{j=1}^{N} \phi_{j}^{2} \sum_{\ell \neq j}^{N} V_{j, \ell}, \tag{11.15}
\end{align*}
$$

where

$$
\begin{equation*}
H^{(N, j)}=-\sum_{\ell=1}^{N} \Delta_{\ell}-\sum_{\ell \neq j}^{N} V_{\ell}+\sum_{k<\ell, k, \ell \neq j}^{N} V_{k, \ell} \tag{11.16}
\end{equation*}
$$

is the Hamiltonian with the $j^{\prime}$ th electron decoupled from the rest of the system. Here we have abbreviated $V_{j}(x)=V_{n e}\left(x_{j}\right)$ and $V_{j, \ell}=V_{e e}\left(x_{j}-x_{\ell}\right)$.

Since $K$ vanishes as $|x| \rightarrow \infty$, we expect it to be relatively compact with respect to the rest. By Lemma 6.23 it suffices to check that it is relatively compact with respect to $H_{0}$. The terms $\left|\partial \phi_{j}\right|^{2}$ are bounded and vanish at $\infty$; hence they are $H_{0}$ compact by Lemma 7.11. However, the terms $\phi_{j}^{2} V_{j}$ have singularities and will be covered by the following lemma.

Lemma 11.5. Let $V$ be a multiplication operator which is $H_{0}$ bounded with $H_{0}$-bound 0 and suppose that $\left\|\chi_{\{x \| x \mid \geq R\}} V R_{H_{0}}(z)\right\| \rightarrow 0$ as $R \rightarrow \infty$. Then $V$ is relatively compact with respect to $H_{0}$.

Proof. Let $\psi_{n}$ converge to 0 weakly. Note that $\left\|\psi_{n}\right\| \leq M$ for some $M>0$. It suffices to show that $\left\|V R_{H_{0}}(z) \psi_{n}\right\|$ converges to 0 . Choose
$\phi \in C_{0}^{\infty}\left(\mathbb{R}^{n},[0,1]\right)$ such that it is one for $|x| \leq R$. Note $\phi \mathfrak{D}\left(H_{0}\right) \subset \mathfrak{D}\left(H_{0}\right)$. Then

$$
\begin{aligned}
\left\|V R_{H_{0}}(z) \psi_{n}\right\| \leq & \left\|(1-\phi) V R_{H_{0}}(z) \psi_{n}\right\|+\left\|V \phi R_{H_{0}}(z) \psi_{n}\right\| \\
\leq & \left\|(1-\phi) V R_{H_{0}}(z)\right\|\left\|\psi_{n}\right\| \\
& +a\left\|H_{0} \phi R_{H_{0}}(z) \psi_{n}\right\|+b\left\|\phi R_{H_{0}}(z) \psi_{n}\right\| .
\end{aligned}
$$

By assumption, the first term can be made smaller than $\varepsilon$ by choosing $R$ large. Next, the same is true for the second term choosing $a$ small since $H_{0} \phi R_{H_{0}}(z)$ is bounded (by Problem 2.9 and the closed graph theorem). Finally, the last term can also be made smaller than $\varepsilon$ by choosing $n$ large since $\phi$ is $H_{0}$ compact.

So $K$ is relatively compact with respect to $H^{(N)}$. In particular $H^{(N)}+$ $K$ is self-adjoint on $H^{2}\left(\mathbb{R}^{3 N}\right)$ and $\sigma_{e s s}\left(H^{(N)}\right)=\sigma_{e s s}\left(H^{(N)}+K\right)$. Since the operators $H^{(N, j)}, 1 \leq j \leq N$, are all of the form $H^{(N-1)}$ plus one particle which does not interact with the others and the nucleus, we have $H^{(N, j)}-\lambda^{N-1} \geq 0,1 \leq j \leq N$. Moreover, we have $P \geq 0$ and hence

$$
\begin{align*}
\left\langle\psi,\left(H^{(N)}+K-\lambda^{N-1}\right) \psi\right\rangle= & \sum_{j=1}^{N}\left\langle\phi_{j} \psi,\left(H^{(N, j)}-\lambda^{N-1}\right) \phi_{j} \psi\right\rangle \\
& +\langle\psi, P \psi\rangle \geq 0 . \tag{11.17}
\end{align*}
$$

Thus we obtain the remaining inclusion

$$
\begin{equation*}
\sigma_{e s s}\left(H^{(N)}\right)=\sigma_{e s s}\left(H^{(N)}+K\right) \subseteq \sigma\left(H^{(N)}+K\right) \subseteq\left[\lambda^{N-1}, \infty\right), \tag{11.18}
\end{equation*}
$$

which finishes the proof of the HVZ theorem.
Note that the same proof works if we add additional nuclei at fixed locations. That is, we can also treat molecules if we assume that the nuclei are fixed in space.

Finally, let us consider the example of helium-like atoms $(N=2)$. By the HVZ theorem and the considerations of the previous section we have

$$
\begin{equation*}
\sigma_{e s s}\left(H^{(2)}\right)=\left[-\frac{\gamma_{n e}^{2}}{4}, \infty\right) . \tag{11.19}
\end{equation*}
$$

Moreover, if $\gamma_{e e}=0$ (no electron interaction), we can take products of oneparticle eigenfunctions to show that

$$
\begin{equation*}
-\gamma_{n e}^{2}\left(\frac{1}{4 n^{2}}+\frac{1}{4 m^{2}}\right) \in \sigma_{p}\left(H^{(2)}\left(\gamma_{e e}=0\right)\right), \quad n, m \in \mathbb{N} \tag{11.20}
\end{equation*}
$$

In particular, there are eigenvalues embedded in the essential spectrum in this case. Moreover, since the electron interaction term is positive, we see

$$
\begin{equation*}
H^{(2)} \geq-\frac{\gamma_{n e}^{2}}{2} \tag{11.21}
\end{equation*}
$$

Note that there can be no positive eigenvalues by the virial theorem. This even holds for arbitrary $N$,

$$
\begin{equation*}
\sigma_{p}\left(H^{(N)}\right) \subset(-\infty, 0) . \tag{11.22}
\end{equation*}
$$

## Chapter 12

## Scattering theory

### 12.1. Abstract theory

In physical measurements one often has the following situation. A particle is shot into a region where it interacts with some forces and then leaves the region again. Outside this region the forces are negligible and hence the time evolution should be asymptotically free. Hence one expects asymptotic states $\psi_{ \pm}(t)=\exp \left(-\mathrm{i} t H_{0}\right) \psi_{ \pm}(0)$ to exist such that

$$
\begin{equation*}
\left\|\psi(t)-\psi_{ \pm}(t)\right\| \rightarrow 0 \quad \text { as } \quad t \rightarrow \pm \infty \tag{12.1}
\end{equation*}
$$

Rewriting this condition, we see

$$
\begin{equation*}
0=\lim _{t \rightarrow \pm \infty}\left\|\mathrm{e}^{-\mathrm{i} t H} \psi(0)-\mathrm{e}^{-\mathrm{i} t H_{0}} \psi_{ \pm}(0)\right\|=\lim _{t \rightarrow \pm \infty}\left\|\psi(0)-\mathrm{e}^{\mathrm{i} t H} \mathrm{e}^{-\mathrm{i} t H_{0}} \psi_{ \pm}(0)\right\| \tag{12.2}
\end{equation*}
$$

and motivated by this, we define the wave operators by

$$
\begin{align*}
\mathfrak{D}\left(\Omega_{ \pm}\right) & =\left\{\psi \in \mathfrak{H} \mid \exists \lim _{t \rightarrow \pm \infty} \mathrm{e}^{\mathrm{i} t H} \mathrm{e}^{-\mathrm{i} t H_{0}} \psi\right\},  \tag{12.3}\\
\Omega_{ \pm} \psi & =\lim _{t \rightarrow \pm \infty} \mathrm{e}^{\mathrm{i} t H} \mathrm{e}^{-\mathrm{i} t H_{0}} \psi .
\end{align*}
$$

The set $\mathfrak{D}\left(\Omega_{ \pm}\right)$is the set of all incoming/outgoing asymptotic states $\psi_{ \pm}$and $\operatorname{Ran}\left(\Omega_{ \pm}\right)$is the set of all states which have an incoming/outgoing asymptotic state. If a state $\psi$ has both, that is, $\psi \in \operatorname{Ran}\left(\Omega_{+}\right) \cap \operatorname{Ran}\left(\Omega_{-}\right)$, it is called a scattering state.

By construction we have

$$
\begin{equation*}
\left\|\Omega_{ \pm} \psi\right\|=\lim _{t \rightarrow \pm \infty}\left\|\mathrm{e}^{\mathrm{i} t H} \mathrm{e}^{-\mathrm{i} t H_{0}} \psi\right\|=\lim _{t \rightarrow \pm \infty}\|\psi\|=\|\psi\| \tag{12.4}
\end{equation*}
$$

and it is not hard to see that $\mathfrak{D}\left(\Omega_{ \pm}\right)$is closed. Moreover, interchanging the roles of $H_{0}$ and $H$ amounts to replacing $\Omega_{ \pm}$by $\Omega_{ \pm}^{-1}$ and hence $\operatorname{Ran}\left(\Omega_{ \pm}\right)$is also closed. In summary,

Lemma 12.1. The sets $\mathfrak{D}\left(\Omega_{ \pm}\right)$and $\operatorname{Ran}\left(\Omega_{ \pm}\right)$are closed and $\Omega_{ \pm}: \mathfrak{D}\left(\Omega_{ \pm}\right) \rightarrow$ $\operatorname{Ran}\left(\Omega_{ \pm}\right)$is unitary.

Next, observe that

$$
\begin{equation*}
\lim _{t \rightarrow \pm \infty} \mathrm{e}^{\mathrm{i} t H} \mathrm{e}^{-\mathrm{i} t H_{0}}\left(\mathrm{e}^{-\mathrm{i} s H_{0}} \psi\right)=\lim _{t \rightarrow \pm \infty} \mathrm{e}^{-\mathrm{i} s H}\left(\mathrm{e}^{\mathrm{i}(t+s) H} \mathrm{e}^{-\mathrm{i}(t+s) H_{0}} \psi\right) \tag{12.5}
\end{equation*}
$$

and hence

$$
\begin{equation*}
\Omega_{ \pm} \mathrm{e}^{-\mathrm{i} t H_{0}} \psi=\mathrm{e}^{-\mathrm{i} t H} \Omega_{ \pm} \psi, \quad \psi \in \mathfrak{D}\left(\Omega_{ \pm}\right) . \tag{12.6}
\end{equation*}
$$

In addition, $\mathfrak{D}\left(\Omega_{ \pm}\right)$is invariant under $\exp \left(-\mathrm{i} t H_{0}\right)$ and $\operatorname{Ran}\left(\Omega_{ \pm}\right)$is invariant under $\exp (-\mathrm{i} t H)$. Moreover, if $\psi \in \mathfrak{D}\left(\Omega_{ \pm}\right)^{\perp}$, then

$$
\begin{equation*}
\left\langle\varphi, \exp \left(-\mathrm{i} t H_{0}\right) \psi\right\rangle=\left\langle\exp \left(\mathrm{i} t H_{0}\right) \varphi, \psi\right\rangle=0, \quad \varphi \in \mathfrak{D}\left(\Omega_{ \pm}\right) . \tag{12.7}
\end{equation*}
$$

Hence $\mathfrak{D}\left(\Omega_{ \pm}\right)^{\perp}$ is invariant under $\exp \left(-\mathrm{i} t H_{0}\right)$ and $\operatorname{Ran}\left(\Omega_{ \pm}\right)^{\perp}$ is invariant under $\exp (-\mathrm{i} t H)$. Consequently, $\mathfrak{D}\left(\Omega_{ \pm}\right)$reduces $\exp \left(-\mathrm{i} t H_{0}\right)$ and $\operatorname{Ran}\left(\Omega_{ \pm}\right)$ reduces $\exp (-\mathrm{i} t H)$. Moreover, differentiating (12.6) with respect to $t$, we obtain from Theorem 5.1 the intertwining property of the wave operators.

Theorem 12.2. The subspaces $\mathfrak{D}\left(\Omega_{ \pm}\right)$, respectively, $\operatorname{Ran}\left(\Omega_{ \pm}\right)$, reduce $H_{0}$, respectively, $H$, and the operators restricted to these subspaces are unitarily equivalent:

$$
\begin{equation*}
\Omega_{ \pm} H_{0} \psi=H \Omega_{ \pm} \psi, \quad \psi \in \mathfrak{D}\left(\Omega_{ \pm}\right) \cap \mathfrak{D}\left(H_{0}\right) . \tag{12.8}
\end{equation*}
$$

It is interesting to know the correspondence between incoming and outgoing states. Hence we define the scattering operator

$$
\begin{equation*}
S=\Omega_{+}^{-1} \Omega_{-}, \quad \mathfrak{D}(S)=\left\{\psi \in \mathfrak{D}\left(\Omega_{-}\right) \mid \Omega_{-} \psi \in \operatorname{Ran}\left(\Omega_{+}\right)\right\} . \tag{12.9}
\end{equation*}
$$

Note that we have $\mathfrak{D}(S)=\mathfrak{D}\left(\Omega_{-}\right)$if and only if $\operatorname{Ran}\left(\Omega_{-}\right) \subseteq \operatorname{Ran}\left(\Omega_{+}\right)$and $\operatorname{Ran}(S)=\mathfrak{D}\left(\Omega_{+}\right)$if and only if $\operatorname{Ran}\left(\Omega_{+}\right) \subseteq \operatorname{Ran}\left(\Omega_{-}\right)$. Moreover, $S$ is unitary from $\mathfrak{D}(S)$ onto $\operatorname{Ran}(S)$ and we have

$$
\begin{equation*}
H_{0} S \psi=S H_{0} \psi, \quad \mathfrak{D}\left(H_{0}\right) \cap \mathfrak{D}(S) \tag{12.10}
\end{equation*}
$$

However, note that this whole theory is meaningless until we can show that the domains $\mathfrak{D}\left(\Omega_{ \pm}\right)$are nontrivial. We first show a criterion due to Cook.

Lemma 12.3 (Cook). Suppose $\mathfrak{D}(H) \subseteq \mathfrak{D}\left(H_{0}\right)$. If

$$
\begin{equation*}
\int_{0}^{\infty}\left\|\left(H-H_{0}\right) \exp \left(\mp \mathrm{i} t H_{0}\right) \psi\right\| d t<\infty, \quad \psi \in \mathfrak{D}\left(H_{0}\right) \tag{12.11}
\end{equation*}
$$

then $\psi \in \mathfrak{D}\left(\Omega_{ \pm}\right)$, respectively. Moreover, we even have

$$
\begin{equation*}
\left\|\left(\Omega_{ \pm}-\mathbb{I}\right) \psi\right\| \leq \int_{0}^{\infty}\left\|\left(H-H_{0}\right) \exp \left(\mp \mathrm{i} t H_{0}\right) \psi\right\| d t \tag{12.12}
\end{equation*}
$$

in this case.
Proof. The result follows from

$$
\begin{equation*}
\mathrm{e}^{\mathrm{i} t H} \mathrm{e}^{-\mathrm{i} t H_{0}} \psi=\psi+\mathrm{i} \int_{0}^{t} \exp (\mathrm{i} s H)\left(H-H_{0}\right) \exp \left(-\mathrm{i} s H_{0}\right) \psi d s \tag{12.13}
\end{equation*}
$$

which holds for $\psi \in \mathfrak{D}\left(H_{0}\right)$.
As a simple consequence we obtain the following result for Schrödinger operators in $\mathbb{R}^{3}$

Theorem 12.4. Suppose $H_{0}$ is the free Schrödinger operator and $H=$ $H_{0}+V$ with $V \in L^{2}\left(\mathbb{R}^{3}\right)$. Then the wave operators exist and $\mathfrak{D}\left(\Omega_{ \pm}\right)=\mathfrak{H}$.

Proof. Since we want to use Cook's lemma, we need to estimate

$$
\|V \psi(s)\|^{2}=\int_{\mathbb{R}^{3}}|V(x) \psi(s, x)|^{2} d x, \quad \psi(s)=\exp \left(\mathrm{i} s H_{0}\right) \psi
$$

for given $\psi \in \mathfrak{D}\left(H_{0}\right)$. Invoking (7.31), we get

$$
\|V \psi(s)\| \leq\|\psi(s)\|_{\infty}\|V\| \leq \frac{1}{(4 \pi s)^{3 / 2}}\|\psi\|_{1}\|V\|, \quad s>0
$$

at least for $\psi \in L^{1}\left(\mathbb{R}^{3}\right)$. Moreover, this implies

$$
\int_{1}^{\infty}\|V \psi(s)\| d s \leq \frac{1}{4 \pi^{3 / 2}}\|\psi\|_{1}\|V\|
$$

and thus any such $\psi$ is in $\mathfrak{D}\left(\Omega_{+}\right)$. Since such functions are dense, we obtain $\mathfrak{D}\left(\Omega_{+}\right)=\mathfrak{H}$, and similarly for $\Omega_{-}$.

By the intertwining property $\psi$ is an eigenfunction of $H_{0}$ if and only if it is an eigenfunction of $H$. Hence for $\psi \in \mathfrak{H}_{p p}\left(H_{0}\right)$ it is easy to check whether it is in $\mathfrak{D}\left(\Omega_{ \pm}\right)$or not and only the continuous subspace is of interest. We will say that the wave operators exist if all elements of $\mathfrak{H}_{a c}\left(H_{0}\right)$ are asymptotic states, that is,

$$
\begin{equation*}
\mathfrak{H}_{a c}\left(H_{0}\right) \subseteq \mathfrak{D}\left(\Omega_{ \pm}\right), \tag{12.14}
\end{equation*}
$$

and that they are complete if, in addition, all elements of $\mathfrak{H}_{a c}(H)$ are scattering states, that is,

$$
\begin{equation*}
\mathfrak{H}_{a c}(H) \subseteq \operatorname{Ran}\left(\Omega_{ \pm}\right) . \tag{12.15}
\end{equation*}
$$

If we even have

$$
\begin{equation*}
\mathfrak{H}_{c}(H) \subseteq \operatorname{Ran}\left(\Omega_{ \pm}\right), \tag{12.16}
\end{equation*}
$$

they are called asymptotically complete.
We will be mainly interested in the case where $H_{0}$ is the free Schrödinger operator and hence $\mathfrak{H}_{a c}\left(H_{0}\right)=\mathfrak{H}$. In this latter case the wave operators exist if $\mathfrak{D}\left(\Omega_{ \pm}\right)=\mathfrak{H}$, they are complete if $\mathfrak{H}_{a c}(H)=\operatorname{Ran}\left(\Omega_{ \pm}\right)$, and they are asymptotically complete if $\mathfrak{H}_{c}(H)=\operatorname{Ran}\left(\Omega_{ \pm}\right)$. In particular, asymptotic completeness implies $\mathfrak{H}_{s c}(H)=\{0\}$ since $H$ restricted to $\operatorname{Ran}\left(\Omega_{ \pm}\right)$is unitarily equivalent to $H_{0}$. Completeness implies that the scattering operator is unitary. Hence, by the intertwining property, kinetic energy is preserved during scattering:

$$
\begin{equation*}
\left\langle\psi_{-}, H_{0} \psi_{-}\right\rangle=\left\langle S \psi_{-}, S H_{0} \psi_{-}\right\rangle=\left\langle S \psi_{-}, H_{0} S \psi_{-}\right\rangle=\left\langle\psi_{+}, H_{0} \psi_{+}\right\rangle \tag{12.17}
\end{equation*}
$$

for $\psi_{-} \in \mathfrak{D}\left(H_{0}\right)$ and $\psi_{+}=S \psi_{-}$.

### 12.2. Incoming and outgoing states

In the remaining sections we want to apply this theory to Schrödinger operators. Our first goal is to give a precise meaning to some terms in the intuitive picture of scattering theory introduced in the previous section.

This physical picture suggests that we should be able to decompose $\psi \in \mathfrak{H}$ into an incoming and an outgoing part. But how should incoming, respectively, outgoing, be defined for $\psi \in \mathfrak{H}$ ? Well, incoming (outgoing) means that the expectation of $x^{2}$ should decrease (increase). Set $x(t)^{2}=$ $\exp \left(\mathrm{i} H_{0} t\right) x^{2} \exp \left(-\mathrm{i} H_{0} t\right)$. Then, abbreviating $\psi(t)=\mathrm{e}^{-\mathrm{i} t H_{0}} \psi$,

$$
\begin{equation*}
\frac{d}{d t} \mathbb{E}_{\psi}\left(x(t)^{2}\right)=\left\langle\psi(t), \mathrm{i}\left[H_{0}, x^{2}\right] \psi(t)\right\rangle=4\langle\psi(t), D \psi(t)\rangle, \quad \psi \in \mathcal{S}\left(\mathbb{R}^{n}\right) \tag{12.18}
\end{equation*}
$$

where $D$ is the dilation operator introduced in (10.9). Hence it is natural to consider $\psi \in \operatorname{Ran}\left(P_{ \pm}\right)$,

$$
\begin{equation*}
P_{ \pm}=P_{D}((0, \pm \infty)) \tag{12.19}
\end{equation*}
$$

as outgoing, respectively, incoming, states. If we project a state in $\operatorname{Ran}\left(P_{ \pm}\right)$ to energies in the interval $\left(a^{2}, b^{2}\right)$, we expect that it cannot be found in a ball of radius proportional to $a|t|$ as $t \rightarrow \pm \infty$ ( $a$ is the minimal velocity of the particle, since we have assumed the mass to be two). In fact, we will show below that the tail decays faster then any inverse power of $|t|$.

We first collect some properties of $D$ which will be needed later on. Note

$$
\begin{equation*}
\mathcal{F} D=-D \mathcal{F} \tag{12.20}
\end{equation*}
$$

and hence $\mathcal{F} f(D)=f(-D) \mathcal{F}$. Additionally, we will look for a transformation which maps $D$ to a multiplication operator.

Since the dilation group acts on $|x|$ only, it seems reasonable to switch to polar coordinates $x=r \omega,(t, \omega) \in \mathbb{R}^{+} \times S^{n-1}$. Since $U(s)$ essentially transforms $r$ into $r \exp (s)$, we will replace $r$ by $\rho=\log (r)$. In these coordinates we have

$$
\begin{equation*}
U(s) \psi\left(\mathrm{e}^{\rho} \omega\right)=\mathrm{e}^{-n s / 2} \psi\left(\mathrm{e}^{(\rho-s)} \omega\right) \tag{12.21}
\end{equation*}
$$

and hence $U(s)$ corresponds to a shift of $\rho$ (the constant in front is absorbed by the volume element). Thus $D$ corresponds to differentiation with respect to this coordinate and all we have to do to make it a multiplication operator is to take the Fourier transform with respect to $\rho$.

This leads us to the Mellin transform

$$
\begin{align*}
\mathcal{M}: L^{2}\left(\mathbb{R}^{n}\right) & \rightarrow L^{2}\left(\mathbb{R} \times S^{n-1}\right),  \tag{12.22}\\
\psi(r \omega) & \rightarrow(\mathcal{M} \psi)(\lambda, \omega)=\frac{1}{\sqrt{2 \pi}} \int_{0}^{\infty} r^{-\mathrm{i} \lambda} \psi(r \omega) r^{\frac{n}{2}-1} d r .
\end{align*}
$$

By construction, $\mathcal{M}$ is unitary; that is,

$$
\begin{equation*}
\int_{\mathbb{R}} \int_{S^{n-1}}|(\mathcal{M} \psi)(\lambda, \omega)|^{2} d \lambda d^{n-1} \omega=\int_{\mathbb{R}^{+}} \int_{S^{n-1}}|\psi(r \omega)|^{2} r^{n-1} d r d^{n-1} \omega, \tag{12.23}
\end{equation*}
$$

where $d^{n-1} \omega$ is the normalized surface measure on $S^{n-1}$. Moreover,

$$
\begin{equation*}
\mathcal{M}^{-1} U(s) \mathcal{M}=\mathrm{e}^{-\mathrm{i} s \lambda} \tag{12.24}
\end{equation*}
$$

and hence

$$
\begin{equation*}
\mathcal{M}^{-1} D \mathcal{M}=\lambda \tag{12.25}
\end{equation*}
$$

From this it is straightforward to show that

$$
\begin{equation*}
\sigma(D)=\sigma_{a c}(D)=\mathbb{R}, \quad \sigma_{s c}(D)=\sigma_{p p}(D)=\emptyset \tag{12.26}
\end{equation*}
$$

and that $\mathcal{S}\left(\mathbb{R}^{n}\right)$ is a core for $D$. In particular we have $P_{+}+P_{-}=\mathbb{I}$.
Using the Mellin transform, we can now prove Perry's estimate.
Lemma 12.5. Suppose $f \in C_{c}^{\infty}(\mathbb{R})$ with $\operatorname{supp}(f) \subset\left(a^{2}, b^{2}\right)$ for some $a, b>$ 0 . For any $R \in \mathbb{R}, N \in \mathbb{N}$ there is a constant $C$ such that

$$
\begin{equation*}
\left\|\chi_{\{x| | x|<2 a| t \mid\}} \mathrm{e}^{-\mathrm{i} t H_{0}} f\left(H_{0}\right) P_{D}(( \pm R, \pm \infty))\right\| \leq \frac{C}{(1+|t|)^{N}}, \quad \pm t \geq 0 \tag{12.27}
\end{equation*}
$$

respectively.
Proof. We prove only the + case, the remaining one being similar. Consider $\psi \in \mathcal{S}\left(\mathbb{R}^{n}\right)$. Introducing

$$
\begin{aligned}
\psi(t, x) & =\mathrm{e}^{-\mathrm{i} t H_{0}} f\left(H_{0}\right) P_{D}((R, \infty)) \psi(x)=\left\langle K_{t, x}, \mathcal{F} P_{D}((R, \infty)) \psi\right\rangle \\
& =\left\langle K_{t, x}, P_{D}((-\infty,-R)) \hat{\psi}\right\rangle
\end{aligned}
$$

where

$$
K_{t, x}(p)=\frac{1}{(2 \pi)^{n / 2}} \mathrm{e}^{\mathrm{i}\left(t p^{2}-p x\right)} f\left(p^{2}\right)^{*},
$$

we see that it suffices to show

$$
\left\|P_{D}((-\infty,-R)) K_{t, x}\right\|^{2} \leq \frac{\text { const }}{(1+|t|)^{2 N}}, \quad \text { for }|x|<2 a|t|, t>0
$$

Now we invoke the Mellin transform to estimate this norm:

$$
\left\|P_{D}((-\infty,-R)) K_{t, x}\right\|^{2}=\int_{-\infty}^{-R} \int_{S^{n-1}}\left|\left(\mathcal{M} K_{t, x}\right)(\lambda, \omega)\right|^{2} d \lambda d^{n-1} \omega
$$

Since

$$
\begin{equation*}
\left(\mathcal{M} K_{t, x}\right)(\lambda, \omega)=\frac{1}{(2 \pi)^{(n+1) / 2}} \int_{0}^{\infty} \tilde{f}(r) \mathrm{e}^{\mathrm{i} \alpha(r)} d r \tag{12.28}
\end{equation*}
$$

with $\tilde{f}(r)=f\left(r^{2}\right)^{*} r^{n / 2-1} \in C_{c}^{\infty}((a, b)), \alpha(r)=t r^{2}+r \omega x-\lambda \log (r)$. Estimating the derivative of $\alpha$, we see

$$
\alpha^{\prime}(r)=2 \operatorname{tr}+\omega x-\lambda / r>0, \quad r \in(a, b),
$$

for $\lambda \leq-R$ and $t>-R(2 \varepsilon a)^{-1}$, where $\varepsilon$ is the distance of $a$ to the support of $\tilde{f}$. Hence we can find a constant such that

$$
\left|\alpha^{\prime}(r)\right| \geq \operatorname{const}(1+|\lambda|+|t|), \quad r \in \operatorname{supp}(\tilde{f})
$$

for $\lambda \leq-R, t>-R(\varepsilon a)^{-1}$. Now the method of stationary phase (Problem 12.1) implies

$$
\left|\left(\mathcal{M} K_{t, x}\right)(\lambda, \omega)\right| \leq \frac{\text { const }}{(1+|\lambda|+|t|)^{N}}
$$

for $\lambda, t$ as before. By increasing the constant, we can even assume that it holds for $t \geq 0$ and $\lambda \leq-R$. This finishes the proof.

Corollary 12.6. Suppose that $f \in C_{c}^{\infty}((0, \infty))$ and $R \in \mathbb{R}$. Then the operator $P_{D}(( \pm R, \pm \infty)) f\left(H_{0}\right) \exp \left(-\mathrm{i} t H_{0}\right)$ converges strongly to 0 as $t \rightarrow$ $\mp \infty$.

Proof. Abbreviating $P_{D}=P_{D}(( \pm R, \pm \infty))$ and $\chi=\chi_{\{x| | x|<2 a| t \mid\}}$, we have

$$
\left\|P_{D} f\left(H_{0}\right) \mathrm{e}^{-\mathrm{i} t H_{0}} \psi\right\| \leq\left\|\chi \mathrm{e}^{\mathrm{i} t H_{0}} f\left(H_{0}\right)^{*} P_{D}\right\|\|\psi\|+\left\|f\left(H_{0}\right)\right\|\|(\mathbb{I}-\chi) \psi\|
$$

since $\|A\|=\left\|A^{*}\right\|$. Taking $t \rightarrow \mp \infty$, the first term goes to zero by our lemma and the second goes to zero since $\chi \psi \rightarrow \psi$.

Problem 12.1 (Method of stationary phase). Consider the integral

$$
I(t)=\int_{-\infty}^{\infty} f(r) \mathrm{e}^{\mathrm{i} t \phi(r)} d r
$$

with $f \in C_{c}^{\infty}(\mathbb{R})$ and a real-valued phase $\phi \in C^{\infty}(\mathbb{R})$. Show that $|I(t)| \leq$ $C_{N} t^{-N}$ for any $N \in \mathbb{N}$ if $\left|\phi^{\prime}(r)\right| \geq 1$ for $r \in \operatorname{supp}(f)$. (Hint: Make a change of variables $\rho=\phi(r)$ and conclude that it suffices to show the case $\phi(r)=r$. Now use integration by parts.)

### 12.3. Schrödinger operators with short range potentials

By the RAGE theorem we know that for $\psi \in \mathfrak{H}_{c}, \psi(t)$ will eventually leave every compact ball (at least on the average). Hence we expect that the time evolution will asymptotically look like the free one for $\psi \in \mathfrak{H}_{c}$ if the potential decays sufficiently fast. In other words, we expect such potentials to be asymptotically complete.

Suppose $V$ is relatively bounded with bound less than one. Introduce

$$
\begin{equation*}
h_{1}(r)=\left\|V R_{H_{0}}(z) \chi_{r}\right\|, \quad h_{2}(r)=\left\|\chi_{r} V R_{H_{0}}(z)\right\|, \quad r \geq 0, \tag{12.29}
\end{equation*}
$$

where

$$
\begin{equation*}
\chi_{r}=\chi_{\{x| | x \mid \geq r\}} . \tag{12.30}
\end{equation*}
$$

The potential $V$ will be called short range if these quantities are integrable. We first note that it suffices to check this for $h_{1}$ or $h_{2}$ and for one $z \in \rho\left(H_{0}\right)$.

Lemma 12.7. The function $h_{1}$ is integrable if and only if $h_{2}$ is. Moreover, $h_{j}$ integrable for one $z_{0} \in \rho\left(H_{0}\right)$ implies $h_{j}$ integrable for all $z \in \rho\left(H_{0}\right)$.

Proof. Pick $\phi \in C_{c}^{\infty}\left(\mathbb{R}^{n},[0,1]\right)$ such that $\phi(x)=0$ for $0 \leq|x| \leq 1 / 2$ and $\phi(x)=\underset{\sim}{0}$ for $1 \leq|x|$. Then it is not hard to see that $h_{j}$ is integrable if and only if $\tilde{h}_{j}$ is integrable, where

$$
\tilde{h}_{1}(r)=\left\|V R_{H_{0}}(z) \phi_{r}\right\|, \quad \tilde{h}_{2}(r)=\left\|\phi_{r} V R_{H_{0}}(z)\right\|, \quad r \geq 1
$$

and $\phi_{r}(x)=\phi(x / r)$. Using

$$
\begin{aligned}
{\left[R_{H_{0}}(z), \phi_{r}\right] } & =-R_{H_{0}}(z)\left[H_{0}(z), \phi_{r}\right] R_{H_{0}}(z) \\
& =R_{H_{0}}(z)\left(\Delta \phi_{r}+\left(\partial \phi_{r}\right) \partial\right) R_{H_{0}}(z)
\end{aligned}
$$

and $\Delta \phi_{r}=\phi_{r / 2} \Delta \phi_{r},\left\|\Delta \phi_{r}\right\|_{\infty} \leq\|\Delta \phi\|_{\infty} / r^{2}$, respectively, $\left(\partial \phi_{r}\right)=\phi_{r / 2}\left(\partial \phi_{r}\right)$, $\left\|\partial \phi_{r}\right\|_{\infty} \leq\|\partial \phi\|_{\infty} / r^{2}$, we see

$$
\left|\tilde{h}_{1}(r)-\tilde{h}_{2}(r)\right| \leq \frac{c}{r} \tilde{h}_{1}(r / 2), \quad r \geq 1 .
$$

Hence $\tilde{h}_{2}$ is integrable if $\tilde{h}_{1}$ is. Conversely,

$$
\tilde{h}_{1}(r) \leq \tilde{h}_{2}(r)+\frac{c}{r} \tilde{h}_{1}(r / 2) \leq \tilde{h}_{2}(r)+\frac{c}{r} \tilde{h}_{2}(r / 2)+\frac{2 c}{r^{2}} \tilde{h}_{1}(r / 4)
$$

shows that $\tilde{h}_{2}$ is integrable if $\tilde{h}_{1}$ is.
Invoking the first resolvent formula

$$
\left\|\phi_{r} V R_{H_{0}}(z)\right\| \leq\left\|\phi_{r} V R_{H_{0}}\left(z_{0}\right)\right\|\left\|\mathbb{I}-\left(z-z_{0}\right) R_{H_{0}}(z)\right\|
$$

finishes the proof.
As a first consequence note
Lemma 12.8. If $V$ is short range, then $R_{H}(z)-R_{H_{0}}(z)$ is compact.

Proof. The operator $R_{H}(z) V\left(\mathbb{I}-\chi_{r}\right) R_{H_{0}}(z)$ is compact since $\left(\mathbb{I}-\chi_{r}\right) R_{H_{0}}(z)$ is by Lemma 7.11 and $R_{H}(z) V$ is bounded by Lemma 6.23. Moreover, by our short range condition it converges in norm to

$$
R_{H}(z) V R_{H_{0}}(z)=R_{H}(z)-R_{H_{0}}(z)
$$

as $r \rightarrow \infty$ (at least for some subsequence).

In particular, by Weyl's theorem we have $\sigma_{\text {ess }}(H)=[0, \infty)$. Moreover, $V$ short range implies that $H$ and $H_{0}$ look alike far outside.

Lemma 12.9. Suppose $R_{H}(z)-R_{H_{0}}(z)$ is compact. Then so is $f(H)-f\left(H_{0}\right)$ for any $f \in C_{\infty}(\mathbb{R})$ and

$$
\begin{equation*}
\lim _{r \rightarrow \infty}\left\|\left(f(H)-f\left(H_{0}\right)\right) \chi_{r}\right\|=0 \tag{12.31}
\end{equation*}
$$

Proof. The first part is Lemma 6.21 and the second part follows from part (ii) of Lemma 6.8 since $\chi_{r}$ converges strongly to 0 .

However, this is clearly not enough to prove asymptotic completeness and we need a more careful analysis.

We begin by showing that the wave operators exist. By Cook's criterion (Lemma 12.3) we need to show that

$$
\begin{align*}
\left\|V \exp \left(\mp \mathrm{i} t H_{0}\right) \psi\right\| \leq & \left\|V R_{H_{0}}(-1)\right\|\left\|\left(\mathbb{I}-\chi_{2 a|t|}\right) \exp \left(\mp \mathrm{i} t H_{0}\right)\left(H_{0}+\mathbb{I}\right) \psi\right\| \\
& +\left\|V R_{H_{0}}(-1) \chi_{2 a|t|}\right\|\left\|\left(H_{0}+\mathbb{I}\right) \psi\right\| \tag{12.32}
\end{align*}
$$

is integrable for a dense set of vectors $\psi$. The second term is integrable by our short range assumption. The same is true by Perry's estimate (Lemma 12.5) for the first term if we choose $\psi=f\left(H_{0}\right) P_{D}(( \pm R, \pm \infty)) \varphi$. Since vectors of this form are dense, we see that the wave operators exist,

$$
\begin{equation*}
\mathfrak{D}\left(\Omega_{ \pm}\right)=\mathfrak{H} \tag{12.33}
\end{equation*}
$$

Since $H$ restricted to $\operatorname{Ran}\left(\Omega_{ \pm}^{*}\right)$ is unitarily equivalent to $H_{0}$, we obtain $[0, \infty)=\sigma_{a c}\left(H_{0}\right) \subseteq \sigma_{a c}(H)$. Furthermore, by $\sigma_{a c}(H) \subseteq \sigma_{e s s}(H)=[0, \infty)$ we even have $\sigma_{a c}(H)=[0, \infty)$.

To prove asymptotic completeness of the wave operators, we will need that the $\left(\Omega_{ \pm}-\mathbb{I}\right) f\left(H_{0}\right) P_{ \pm}$are compact.

Lemma 12.10. Let $f \in C_{c}^{\infty}((0, \infty))$ and suppose $\psi_{n}$ converges weakly to 0 . Then

$$
\begin{equation*}
\lim _{n \rightarrow \infty}\left\|\left(\Omega_{ \pm}-\mathbb{I}\right) f\left(H_{0}\right) P_{ \pm} \psi_{n}\right\|=0 \tag{12.34}
\end{equation*}
$$

that is, $\left(\Omega_{ \pm}-\mathbb{I}\right) f\left(H_{0}\right) P_{ \pm}$is compact.

Proof. By (12.13) we see

$$
\left\|R_{H}(z)\left(\Omega_{ \pm}-\mathbb{I}\right) f\left(H_{0}\right) P_{ \pm} \psi_{n}\right\| \leq \int_{0}^{\infty}\left\|R_{H}(z) V \exp \left(-\mathrm{i} s H_{0}\right) f\left(H_{0}\right) P_{ \pm} \psi_{n}\right\| d t
$$

Since $R_{H}(z) V R_{H_{0}}$ is compact, we see that the integrand

$$
\begin{aligned}
& R_{H}(z) V \exp \left(-\mathrm{i} s H_{0}\right) f\left(H_{0}\right) P_{ \pm} \psi_{n} \\
& \quad=R_{H}(z) V R_{H_{0}} \exp \left(-\mathrm{i} s H_{0}\right)\left(H_{0}+1\right) f\left(H_{0}\right) P_{ \pm} \psi_{n}
\end{aligned}
$$

converges pointwise to 0 . Moreover, arguing as in (12.32), the integrand is bounded by an $L^{1}$ function depending only on $\left\|\psi_{n}\right\|$. Thus $R_{H}(z)\left(\Omega_{ \pm}-\right.$ $\mathbb{I}) f\left(H_{0}\right) P_{ \pm}$is compact by the dominated convergence theorem. Furthermore, using the intertwining property, we see that

$$
\begin{aligned}
\left(\Omega_{ \pm}-\mathbb{I}\right) \tilde{f}\left(H_{0}\right) P_{ \pm}= & R_{H}(z)\left(\Omega_{ \pm}-\mathbb{I}\right) f\left(H_{0}\right) P_{ \pm} \\
& -\left(R_{H}(z)-R_{H_{0}}(z)\right) f\left(H_{0}\right) P_{ \pm}
\end{aligned}
$$

is compact by Lemma 6.21, where $\tilde{f}(\lambda)=(\lambda+1) f(\lambda)$.
Now we have gathered enough information to tackle the problem of asymptotic completeness.

We first show that the singular continuous spectrum is absent. This is not really necessary, but it avoids the use of Cesàro means in our main argument.

Abbreviate $P=P_{H}^{s c} P_{H}((a, b)), 0<a<b$. Since $H$ restricted to $\operatorname{Ran}\left(\Omega_{ \pm}\right)$is unitarily equivalent to $H_{0}$ (which has purely absolutely continuous spectrum), the singular part must live on $\operatorname{Ran}\left(\Omega_{ \pm}\right)^{\perp}$; that is, $P_{H}^{s c} \Omega_{ \pm}=0$. Thus $P f\left(H_{0}\right)=P\left(\mathbb{I}-\Omega_{+}\right) f\left(H_{0}\right) P_{+}+P\left(\mathbb{I}-\Omega_{-}\right) f\left(H_{0}\right) P_{-}$is compact. Since $f(H)-f\left(H_{0}\right)$ is compact, it follows that $P f(H)$ is also compact. Choosing $f$ such that $f(\lambda)=1$ for $\lambda \in[a, b]$, we see that $P=P f(H)$ is compact and hence finite dimensional. In particular $\sigma_{s c}(H) \cap(a, b)$ is a finite set. But a continuous measure cannot be supported on a finite set, showing $\sigma_{s c}(H) \cap(a, b)=\emptyset$. Since $0<a<b$ are arbitrary, we even have $\sigma_{s c}(H) \cap(0, \infty)=\emptyset$ and by $\sigma_{s c}(H) \subseteq \sigma_{e s s}(H)=[0, \infty)$, we obtain $\sigma_{s c}(H)=\emptyset$.

Observe that replacing $P_{H}^{s c}$ by $P_{H}^{p p}$, the same argument shows that all nonzero eigenvalues are finite dimensional and cannot accumulate in $(0, \infty)$.

In summary we have shown
Theorem 12.11. Suppose $V$ is short range. Then

$$
\begin{equation*}
\sigma_{a c}(H)=\sigma_{\text {ess }}(H)=[0, \infty), \quad \sigma_{s c}(H)=\emptyset . \tag{12.35}
\end{equation*}
$$

All nonzero eigenvalues have finite multiplicity and cannot accumulate in $(0, \infty)$.

Now we come to the anticipated asymptotic completeness result of Enß. Choose

$$
\begin{equation*}
\psi \in \mathfrak{H}_{c}(H)=\mathfrak{H}_{a c}(H) \quad \text { such that } \quad \psi=f(H) \psi \tag{12.36}
\end{equation*}
$$

for some $f \in C_{c}^{\infty}((0, \infty))$. By the RAGE theorem the sequence $\psi(t)$ converges weakly to zero as $t \rightarrow \pm \infty$. Abbreviate $\psi(t)=\exp (-\mathrm{i} t H) \psi$. Introduce

$$
\begin{equation*}
\varphi_{ \pm}(t)=f\left(H_{0}\right) P_{ \pm} \psi(t) \tag{12.37}
\end{equation*}
$$

which satisfy

$$
\begin{equation*}
\lim _{t \rightarrow \pm \infty}\left\|\psi(t)-\varphi_{+}(t)-\varphi_{-}(t)\right\|=0 \tag{12.38}
\end{equation*}
$$

Indeed this follows from

$$
\begin{equation*}
\psi(t)=\varphi_{+}(t)+\varphi_{-}(t)+\left(f(H)-f\left(H_{0}\right)\right) \psi(t) \tag{12.39}
\end{equation*}
$$

and Lemma 6.21. Moreover, we even have

$$
\begin{equation*}
\lim _{t \rightarrow \pm \infty}\left\|\left(\Omega_{ \pm}-\mathbb{I}\right) \varphi_{ \pm}(t)\right\|=0 \tag{12.40}
\end{equation*}
$$

by Lemma 12.10. Now suppose $\psi \in \operatorname{Ran}\left(\Omega_{ \pm}\right)^{\perp}$. Then

$$
\begin{align*}
\|\psi\|^{2} & =\lim _{t \rightarrow \pm \infty}\langle\psi(t), \psi(t)\rangle \\
& =\lim _{t \rightarrow \pm \infty}\left\langle\psi(t), \varphi_{+}(t)+\varphi_{-}(t)\right\rangle \\
& =\lim _{t \rightarrow \pm \infty}\left\langle\psi(t), \Omega_{+} \varphi_{+}(t)+\Omega_{-} \varphi_{-}(t)\right\rangle . \tag{12.41}
\end{align*}
$$

By Theorem 12.2, $\operatorname{Ran}\left(\Omega_{ \pm}\right)^{\perp}$ is invariant under $H$ and thus $\psi(t) \in \operatorname{Ran}\left(\Omega_{ \pm}\right)^{\perp}$ implying

$$
\begin{align*}
\|\psi\|^{2} & =\lim _{t \rightarrow \pm \infty}\left\langle\psi(t), \Omega_{\mp} \varphi_{\mp}(t)\right\rangle  \tag{12.42}\\
& =\lim _{t \rightarrow \pm \infty}\left\langle P_{\mp} f\left(H_{0}\right)^{*} \Omega_{\mp}^{*} \psi(t), \psi(t)\right\rangle .
\end{align*}
$$

Invoking the intertwining property, we see

$$
\begin{equation*}
\|\psi\|^{2}=\lim _{t \rightarrow \pm \infty}\left\langle P_{\mp} f\left(H_{0}\right)^{*} \mathrm{e}^{-\mathrm{i} t H_{0}} \Omega_{\mp}^{*} \psi, \psi(t)\right\rangle=0 \tag{12.43}
\end{equation*}
$$

by Corollary 12.6. Hence $\operatorname{Ran}\left(\Omega_{ \pm}\right)=\mathfrak{H}_{a c}(H)=\mathfrak{H}_{c}(H)$ and we thus have shown

Theorem 12.12 (Enß). Suppose $V$ is short range. Then the wave operators are asymptotically complete.

## Part 3

## Appendix

# Appendix $A$ 

## Almost everything about Lebesgue integration

In this appendix I give a brief introduction to measure theory. Good references are [7], [32], or [47].

## A.1. Borel measures in a nut shell

The first step in defining the Lebesgue integral is extending the notion of size from intervals to arbitrary sets. Unfortunately, this turns out to be too much, since a classical paradox by Banach and Tarski shows that one can break the unit ball in $\mathbb{R}^{3}$ into a finite number of (wild - choosing the pieces uses the Axiom of Choice and cannot be done with a jigsaw;-) pieces, rotate and translate them, and reassemble them to get two copies of the unit ball (compare Problem A.1). Hence any reasonable notion of size (i.e., one which is translation and rotation invariant) cannot be defined for all sets!

A collection of subsets $\mathcal{A}$ of a given set $X$ such that

- $X \in \mathcal{A}$,
- $\mathcal{A}$ is closed under finite unions,
- $\mathcal{A}$ is closed under complements
is called an algebra. Note that $\emptyset \in \mathcal{A}$ and that, by de Morgan, $\mathcal{A}$ is also closed under finite intersections. If an algebra is closed under countable unions (and hence also countable intersections), it is called a $\sigma$-algebra.

Moreover, the intersection of any family of ( $\sigma$-)algebras $\left\{\mathcal{A}_{\alpha}\right\}$ is again a $(\sigma$-)algebra and for any collection $S$ of subsets there is a unique smallest $(\sigma$-)algebra $\Sigma(S)$ containing $S$ (namely the intersection of all ( $\sigma$-)algebras containing $S$ ). It is called the ( $\sigma$-)algebra generated by $S$.

If $X$ is a topological space, the Borel $\sigma$-algebra of $X$ is defined to be the $\sigma$-algebra generated by all open (respectively, all closed) sets. Sets in the Borel $\sigma$-algebra are called Borel sets.
Example. In the case $X=\mathbb{R}^{n}$ the Borel $\sigma$-algebra will be denoted by $\mathfrak{B}^{n}$ and we will abbreviate $\mathfrak{B}=\mathfrak{B}^{1}$.

Now let us turn to the definition of a measure: A set $X$ together with a $\sigma$-algebra $\Sigma$ is called a measurable space. A measure $\mu$ is a map $\mu: \Sigma \rightarrow[0, \infty]$ on a $\sigma$-algebra $\Sigma$ such that

$$
\begin{aligned}
& \text { - } \mu(\emptyset)=0, \\
& \text { - } \mu\left(\bigcup_{j=1}^{\infty} A_{j}\right)=\sum_{j=1}^{\infty} \mu\left(A_{j}\right) \text { if } A_{j} \cap A_{k}=\emptyset \text { for all } j \neq k(\sigma \text {-additivity }) .
\end{aligned}
$$

It is called $\sigma$-finite if there is a countable cover $\left\{X_{j}\right\}_{j=1}^{\infty}$ of $X$ with $\mu\left(X_{j}\right)<$ $\infty$ for all $j$. (Note that it is no restriction to assume $X_{j} \subseteq X_{j+1}$.) It is called finite if $\mu(X)<\infty$. The sets in $\Sigma$ are called measurable sets and the triple $X, \Sigma$, and $\mu$ is referred to as a measure space.

If we replace the $\sigma$-algebra by an algebra $\mathcal{A}$, then $\mu$ is called a premeasure. In this case $\sigma$-additivity clearly only needs to hold for disjoint sets $A_{n}$ for which $\bigcup_{n} A_{n} \in \mathcal{A}$.

We will write $A_{n} \nearrow A$ if $A_{n} \subseteq A_{n+1}\left(\right.$ note $\left.A=\bigcup_{n} A_{n}\right)$ and $A_{n} \searrow A$ if $A_{n+1} \subseteq A_{n}\left(\right.$ note $\left.A=\bigcap_{n} A_{n}\right)$.

Theorem A.1. Any measure $\mu$ satisfies the following properties:
(i) $A \subseteq B$ implies $\mu(A) \leq \mu(B)$ (monotonicity).
(ii) $\mu\left(A_{n}\right) \rightarrow \mu(A)$ if $A_{n} \nearrow A$ (continuity from below).
(iii) $\mu\left(A_{n}\right) \rightarrow \mu(A)$ if $A_{n} \searrow A$ and $\mu\left(A_{1}\right)<\infty$ (continuity from above).

Proof. The first claim is obvious. The second follows using $\tilde{A}_{n}=A_{n} \backslash A_{n-1}$ and $\sigma$-additivity. The third follows from the second using $\tilde{A}_{n}=A_{1} \backslash A_{n}$ and $\mu\left(\tilde{A}_{n}\right)=\mu\left(A_{1}\right)-\mu\left(A_{n}\right)$.

Example. Let $A \in \mathfrak{P}(M)$ and set $\mu(A)$ to be the number of elements of $A$ (respectively, $\infty$ if $A$ is infinite). This is the so-called counting measure.

Note that if $X=\mathbb{N}$ and $A_{n}=\{j \in \mathbb{N} \mid j \geq n\}$, then $\mu\left(A_{n}\right)=\infty$, but $\mu\left(\bigcap_{n} A_{n}\right)=\mu(\emptyset)=0$ which shows that the requirement $\mu\left(A_{1}\right)<\infty$ in the last claim of Theorem A. 1 is not superfluous.

A measure on the Borel $\sigma$-algebra is called a Borel measure if $\mu(C)<$ $\infty$ for any compact set $C$. A Borel measures is called outer regular if

$$
\begin{equation*}
\mu(A)=\inf _{A \subseteq O, O \text { open }} \mu(O) \tag{A.1}
\end{equation*}
$$

and inner regular if

$$
\begin{equation*}
\mu(A)=\sup _{C \subseteq A, C \text { compact }} \mu(C) . \tag{A.2}
\end{equation*}
$$

It is called regular if it is both outer and inner regular.
But how can we obtain some more interesting Borel measures? We will restrict ourselves to the case of $X=\mathbb{R}$ for simplicity. Then the strategy is as follows: Start with the algebra of finite unions of disjoint intervals and define $\mu$ for those sets (as the sum over the intervals). This yields a premeasure. Extend this to an outer measure for all subsets of $\mathbb{R}$. Show that the restriction to the Borel sets is a measure.

Let us first show how we should define $\mu$ for intervals: To every Borel measure on $\mathfrak{B}$ we can assign its distribution function

$$
\mu(x)= \begin{cases}-\mu((x, 0]), & x<0  \tag{A.3}\\ 0, & x=0 \\ \mu((0, x]), & x>0\end{cases}
$$

which is right continuous and nondecreasing. Conversely, given a right continuous nondecreasing function $\mu: \mathbb{R} \rightarrow \mathbb{R}$, we can set

$$
\mu(A)= \begin{cases}\mu(b)-\mu(a), & A=(a, b],  \tag{A.4}\\ \mu(b)-\mu(a-), & A=[a, b], \\ \mu(b-)-\mu(a), & A=(a, b), \\ \mu(b-)-\mu(a-), & A=[a, b),\end{cases}
$$

where $\mu(a-)=\lim _{\varepsilon \downarrow 0} \mu(a-\varepsilon)$. In particular, this gives a premeasure on the algebra of finite unions of intervals which can be extended to a measure:

Theorem A.2. For every right continuous nondecreasing function $\mu: \mathbb{R} \rightarrow$ $\mathbb{R}$ there exists a unique regular Borel measure $\mu$ which extends (A.4). Two different functions generate the same measure if and only if they differ by a constant.

Since the proof of this theorem is rather involved, we defer it to the next section and look at some examples first.
Example. Suppose $\Theta(x)=0$ for $x<0$ and $\Theta(x)=1$ for $x \geq 0$. Then we obtain the so-called Dirac measure at 0 , which is given by $\Theta(A)=1$ if $0 \in A$ and $\Theta(A)=0$ if $0 \notin A$.

Example. Suppose $\lambda(x)=x$. Then the associated measure is the ordinary Lebesgue measure on $\mathbb{R}$. We will abbreviate the Lebesgue measure of a Borel set $A$ by $\lambda(A)=|A|$.

It can be shown that Borel measures on a locally compact second countable space are always regular ([7, Thm. 29.12]).

A set $A \in \Sigma$ is called a support for $\mu$ if $\mu(X \backslash A)=0$. A property is said to hold $\mu$-almost everywhere (a.e.) if it holds on a support for $\mu$ or, equivalently, if the set where it does not hold is contained in a set of measure zero.
Example. The set of rational numbers has Lebesgue measure zero: $\lambda(\mathbb{Q})=$ 0 . In fact, any single point has Lebesgue measure zero, and so has any countable union of points (by countable additivity).

Example. The Cantor set is an example of a closed uncountable set of Lebesgue measure zero. It is constructed as follows: Start with $C_{0}=[0,1]$ and remove the middle third to obtain $C_{1}=\left[0, \frac{1}{3}\right] \cup\left[\frac{2}{3}, 1\right]$. Next, again remove the middle third's of the remaining sets to obtain $C_{2}=\left[0, \frac{1}{9}\right] \cup\left[\frac{2}{9}, \frac{1}{3}\right] \cup\left[\frac{2}{3}, \frac{7}{9}\right] \cup$ $\left[\frac{8}{9}, 1\right]$ :

Proceeding like this, we obtain a sequence of nesting sets $C_{n}$ and the limit $C=\bigcap_{n} C_{n}$ is the Cantor set. Since $C_{n}$ is compact, so is $C$. Moreover, $C_{n}$ consists of $2^{n}$ intervals of length $3^{-n}$, and thus its Lebesgue measure is $\lambda\left(C_{n}\right)=(2 / 3)^{n}$. In particular, $\lambda(C)=\lim _{n \rightarrow \infty} \lambda\left(C_{n}\right)=0$. Using the ternary expansion, it is extremely simple to describe: $C$ is the set of all $x \in[0,1]$ whose ternary expansion contains no one's, which shows that $C$ is uncountable (why?). It has some further interesting properties: it is totally disconnected (i.e., it contains no subintervals) and perfect (it has no isolated points).

Problem A. 1 (Vitali set). Call two numbers $x, y \in[0,1)$ equivalent if $x-y$ is rational. Construct the set $V$ by choosing one representative from each equivalence class. Show that $V$ cannot be measurable with respect to any nontrivial finite translation invariant measure on $[0,1)$. (Hint: How can you build up $[0,1)$ from translations of $V$ ?)

## A.2. Extending a premeasure to a measure

The purpose of this section is to prove Theorem A.2. It is rather technical and should be skipped on first reading.

In order to prove Theorem A.2, we need to show how a premeasure can be extended to a measure. As a prerequisite we first establish that it suffices to check increasing (or decreasing) sequences of sets when checking whether a given algebra is in fact a $\sigma$-algebra:

A collection of sets $\mathcal{M}$ is called a monotone class if $A_{n} \nearrow A$ implies $A \in \mathcal{M}$ whenever $A_{n} \in \mathcal{M}$ and $A_{n} \searrow A$ implies $A \in \mathcal{M}$ whenever $A_{n} \in \mathcal{M}$. Every $\sigma$-algebra is a monotone class and the intersection of monotone classes is a monotone class. Hence every collection of sets $S$ generates a smallest monotone class $\mathcal{M}(S)$.
Theorem A.3. Let $\mathcal{A}$ be an algebra. Then $\mathcal{M}(\mathcal{A})=\Sigma(\mathcal{A})$.
Proof. We first show that $\mathcal{M}=\mathcal{M}(\mathcal{A})$ is an algebra.
Put $M(A)=\{B \in \mathcal{M} \mid A \cup B \in \mathcal{M}\}$. If $B_{n}$ is an increasing sequence of sets in $M(A)$, then $A \cup B_{n}$ is an increasing sequence in $\mathcal{M}$ and hence $\bigcup_{n}\left(A \cup B_{n}\right) \in \mathcal{M}$. Now

$$
A \cup\left(\bigcup_{n} B_{n}\right)=\bigcup_{n}\left(A \cup B_{n}\right)
$$

shows that $M(A)$ is closed under increasing sequences. Similarly, $M(A)$ is closed under decreasing sequences and hence it is a monotone class. But does it contain any elements? Well, if $A \in \mathcal{A}$, we have $\mathcal{A} \subseteq M(A)$ implying $M(A)=\mathcal{M}$ for $A \in \mathcal{A}$. Hence $A \cup B \in \mathcal{M}$ if at least one of the sets is in $\mathcal{A}$. But this shows $\mathcal{A} \subseteq M(A)$ and hence $M(A)=\mathcal{M}$ for any $A \in \mathcal{M}$. So $\mathcal{M}$ is closed under finite unions.

To show that we are closed under complements, consider $M=\{A \in$ $\mathcal{M} \mid X \backslash A \in \mathcal{M}\}$. If $A_{n}$ is an increasing sequence, then $X \backslash A_{n}$ is a decreasing sequence and $X \backslash \bigcup_{n} A_{n}=\bigcap_{n} X \backslash A_{n} \in \mathcal{M}$ if $A_{n} \in M$ and similarly for decreasing sequences. Hence $M$ is a monotone class and must be equal to $\mathcal{M}$ since it contains $\mathcal{A}$.

So we know that $\mathcal{M}$ is an algebra. To show that it is a $\sigma$-algebra, let $A_{n} \in \mathcal{M}$ be given and put $\tilde{A}_{n}=\bigcup_{k \leq n} A_{n} \in \mathcal{M}$. Then $\tilde{A}_{n}$ is increasing and $\bigcup_{n} \tilde{A}_{n}=\bigcup_{n} A_{n} \in \mathcal{M}$.

The typical use of this theorem is as follows: First verify some property for sets in an algebra $\mathcal{A}$. In order to show that it holds for any set in $\Sigma(\mathcal{A})$, it suffices to show that the collection of sets for which it holds is closed under countable increasing and decreasing sequences (i.e., is a monotone class).

Now we start by proving that (A.4) indeed gives rise to a premeasure.

Lemma A.4. The interval function $\mu$ defined in (A.4) gives rise to a unique $\sigma$-finite regular premeasure on the algebra $\mathcal{A}$ of finite unions of disjoint intervals.

Proof. First of all, (A.4) can be extended to finite unions of disjoint intervals by summing over all intervals. It is straightforward to verify that $\mu$ is well-defined (one set can be represented by different unions of intervals) and by construction additive.

To show regularity, we can assume any such union to consist of open intervals and points only. To show outer regularity, replace each point $\{x\}$ by a small open interval $(x+\varepsilon, x-\varepsilon)$ and use that $\mu(\{x\})=\lim _{\varepsilon \downarrow 0} \mu(x+\varepsilon)-$ $\mu(x-\varepsilon)$. Similarly, to show inner regularity, replace each open interval ( $a, b$ ) by a compact one, $\left[a_{n}, b_{n}\right] \subseteq(a, b)$, and use $\mu((a, b))=\lim _{n \rightarrow \infty} \mu\left(b_{n}\right)-\mu\left(a_{n}\right)$ if $a_{n} \downarrow a$ and $b_{n} \uparrow b$.

It remains to verify $\sigma$-additivity. We need to show

$$
\mu\left(\bigcup_{k} I_{k}\right)=\sum_{k} \mu\left(I_{k}\right)
$$

whenever $I_{n} \in \mathcal{A}$ and $I=\bigcup_{k} I_{k} \in \mathcal{A}$. Since each $I_{n}$ is a finite union of intervals, we can as well assume each $I_{n}$ is just one interval (just split $I_{n}$ into its subintervals and note that the sum does not change by additivity). Similarly, we can assume that $I$ is just one interval (just treat each subinterval separately).

By additivity $\mu$ is monotone and hence

$$
\sum_{k=1}^{n} \mu\left(I_{k}\right)=\mu\left(\bigcup_{k=1}^{n} I_{k}\right) \leq \mu(I)
$$

which shows

$$
\sum_{k=1}^{\infty} \mu\left(I_{k}\right) \leq \mu(I)
$$

To get the converse inequality, we need to work harder.
By outer regularity we can cover each $I_{k}$ by some open interval $J_{k}$ such that $\mu\left(J_{k}\right) \leq \mu\left(I_{k}\right)+\frac{\varepsilon}{2^{k}}$. First suppose $I$ is compact. Then finitely many of the $J_{k}$, say the first $n$, cover $I$ and we have

$$
\mu(I) \leq \mu\left(\bigcup_{k=1}^{n} J_{k}\right) \leq \sum_{k=1}^{n} \mu\left(J_{k}\right) \leq \sum_{k=1}^{\infty} \mu\left(I_{k}\right)+\varepsilon .
$$

Since $\varepsilon>0$ is arbitrary, this shows $\sigma$-additivity for compact intervals. By additivity we can always add/subtract the endpoints of $I$ and hence $\sigma$ additivity holds for any bounded interval. If $I$ is unbounded, say $I=[a, \infty)$,
then given $x>0$, we can find an $n$ such that $J_{n}$ cover at least $[0, x]$ and hence

$$
\sum_{k=1}^{n} \mu\left(I_{k}\right) \geq \sum_{k=1}^{n} \mu\left(J_{k}\right)-\varepsilon \geq \mu([a, x])-\varepsilon .
$$

Since $x>a$ and $\varepsilon>0$ are arbitrary, we are done.
This premeasure determines the corresponding measure $\mu$ uniquely (if there is one at all):

Theorem A. 5 (Uniqueness of measures). Let $\mu$ be a $\sigma$-finite premeasure on an algebra $\mathcal{A}$. Then there is at most one extension to $\Sigma(\mathcal{A})$.

Proof. We first assume that $\mu(X)<\infty$. Suppose there is another extension $\tilde{\mu}$ and consider the set

$$
S=\{A \in \Sigma(\mathcal{A}) \mid \mu(A)=\tilde{\mu}(A)\} .
$$

I claim $S$ is a monotone class and hence $S=\Sigma(\mathcal{A})$ since $\mathcal{A} \subseteq S$ by assumption (Theorem A.3).

Let $A_{n} \nearrow A$. If $A_{n} \in S$, we have $\mu\left(A_{n}\right)=\tilde{\mu}\left(A_{n}\right)$ and taking limits (Theorem A. 1 (ii)), we conclude $\mu(A)=\tilde{\mu}(A)$. Next let $A_{n} \searrow A$ and take limits again. This finishes the finite case. To extend our result to the $\sigma$-finite case, let $X_{j} \nearrow X$ be an increasing sequence such that $\mu\left(X_{j}\right)<\infty$. By the finite case $\mu\left(A \cap X_{j}\right)=\tilde{\mu}\left(A \cap X_{j}\right)$ (just restrict $\mu, \tilde{\mu}$ to $\left.X_{j}\right)$. Hence

$$
\mu(A)=\lim _{j \rightarrow \infty} \mu\left(A \cap X_{j}\right)=\lim _{j \rightarrow \infty} \tilde{\mu}\left(A \cap X_{j}\right)=\tilde{\mu}(A)
$$

and we are done.
Note that if our premeasure is regular, so will the extension be:
Lemma A.6. Suppose $\mu$ is a $\sigma$-finite measure on the Borel sets $\mathfrak{B}$. Then outer (inner) regularity holds for all Borel sets if it holds for all sets in some algebra $\mathcal{A}$ generating the Borel sets $\mathfrak{B}$.

Proof. We first assume that $\mu(X)<\infty$. Set

$$
\mu^{\circ}(A)=\inf _{A \subseteq O, O \text { open }} \mu(O) \geq \mu(A)
$$

and let $M=\left\{A \in \mathfrak{B} \mid \mu^{\circ}(A)=\mu(A)\right\}$. Since by assumption $M$ contains some algebra generating $\mathfrak{B}$, it suffices to prove that $M$ is a monotone class.

Let $A_{n} \in M$ be a monotone sequence and let $O_{n} \supseteq A_{n}$ be open sets such that $\mu\left(O_{n}\right) \leq \mu\left(A_{n}\right)+\frac{\varepsilon}{2^{n}}$. Then

$$
\mu\left(A_{n}\right) \leq \mu\left(O_{n}\right) \leq \mu\left(A_{n}\right)+\frac{\varepsilon}{2^{n}} .
$$

Now if $A_{n} \searrow A$, just take limits and use continuity from below of $\mu$ to see that $O_{n} \supseteq A_{n} \supseteq A$ is a sequence of open sets with $\mu\left(O_{n}\right) \rightarrow \mu(A)$. Similarly if $A_{n} \nearrow A$, observe that $O=\bigcup_{n} O_{n}$ satisfies $O \supseteq A$ and

$$
\mu(O) \leq \mu(A)+\sum \mu\left(O_{n} \backslash A\right) \leq \mu(A)+\varepsilon
$$

since $\mu\left(O_{n} \backslash A\right) \leq \mu\left(O_{n} \backslash A_{n}\right) \leq \frac{\varepsilon}{2^{n}}$.
Next let $\mu$ be arbitrary. Let $X_{j}$ be a cover with $\mu\left(X_{j}\right)<\infty$. Given $A$, we can split it into disjoint sets $A_{j}$ such that $A_{j} \subseteq X_{j}\left(A_{1}=A \cap X_{1}\right.$, $A_{2}=\left(A \backslash A_{1}\right) \cap X_{2}$, etc.). By regularity, we can assume $X_{j}$ open. Thus there are open (in $X$ ) sets $O_{j}$ covering $A_{j}$ such that $\mu\left(O_{j}\right) \leq \mu\left(A_{j}\right)+\frac{\varepsilon}{2^{j}}$. Then $O=\bigcup_{j} O_{j}$ is open, covers $A$, and satisfies

$$
\mu(A) \leq \mu(O) \leq \sum_{j} \mu\left(O_{j}\right) \leq \mu(A)+\varepsilon .
$$

This settles outer regularity.
Next let us turn to inner regularity. If $\mu(X)<\infty$, one can show as before that $M=\left\{A \in \mathfrak{B} \mid \mu_{\circ}(A)=\mu(A)\right\}$, where

$$
\mu_{\circ}(A)=\sup _{C \subseteq A, C \text { compact }} \mu(C) \leq \mu(A)
$$

is a monotone class. This settles the finite case.
For the $\sigma$-finite case split $A$ again as before. Since $X_{j}$ has finite measure, there are compact subsets $K_{j}$ of $A_{j}$ such that $\mu\left(A_{j}\right) \leq \mu\left(K_{j}\right)+\frac{\varepsilon}{2 j}$. Now we need to distinguish two cases: If $\mu(A)=\infty$, the sum $\sum_{j} \mu\left(A_{j}\right)$ will diverge and so will $\sum_{j} \mu\left(K_{j}\right)$. Hence $\tilde{K}_{n}=\bigcup_{j=1}^{n} \subseteq A$ is compact with $\mu\left(\tilde{K}_{n}\right) \rightarrow \infty=\mu(A)$. If $\mu(A)<\infty$, the sum $\sum_{j} \mu\left(A_{j}\right)$ will converge and choosing $n$ sufficiently large, we will have

$$
\mu\left(\tilde{K}_{n}\right) \leq \mu(A) \leq \mu\left(\tilde{K}_{n}\right)+2 \varepsilon .
$$

This finishes the proof.
So it remains to ensure that there is an extension at all. For any premeasure $\mu$ we define

$$
\begin{equation*}
\mu^{*}(A)=\inf \left\{\sum_{n=1}^{\infty} \mu\left(A_{n}\right) \mid A \subseteq \bigcup_{n=1}^{\infty} A_{n}, A_{n} \in \mathcal{A}\right\} \tag{A.5}
\end{equation*}
$$

where the infimum extends over all countable covers from $\mathcal{A}$. Then the function $\mu^{*}: \mathfrak{P}(X) \rightarrow[0, \infty]$ is an outer measure; that is, it has the properties (Problem A.2)

- $\mu^{*}(\emptyset)=0$,
- $A_{1} \subseteq A_{2} \Rightarrow \mu^{*}\left(A_{1}\right) \leq \mu^{*}\left(A_{2}\right)$, and
- $\mu^{*}\left(\bigcup_{n=1}^{\infty} A_{n}\right) \leq \sum_{n=1}^{\infty} \mu^{*}\left(A_{n}\right) \quad$ (subadditivity).

Note that $\mu^{*}(A)=\mu(A)$ for $A \in \mathcal{A}$ (Problem A.3).
Theorem A. 7 (Extensions via outer measures). Let $\mu^{*}$ be an outer measure. Then the set $\Sigma$ of all sets $A$ satisfying the Carathéodory condition

$$
\begin{equation*}
\mu^{*}(E)=\mu^{*}(A \cap E)+\mu^{*}\left(A^{\prime} \cap E\right), \quad \forall E \subseteq X \tag{A.6}
\end{equation*}
$$

(where $A^{\prime}=X \backslash A$ is the complement of $A$ ) forms a $\sigma$-algebra and $\mu^{*}$ restricted to this $\sigma$-algebra is a measure.

Proof. We first show that $\Sigma$ is an algebra. It clearly contains $X$ and is closed under complements. Let $A, B \in \Sigma$. Applying Carathéodory's condition twice finally shows

$$
\begin{aligned}
\mu^{*}(E)= & \mu^{*}(A \cap B \cap E)+\mu^{*}\left(A^{\prime} \cap B \cap E\right)+\mu^{*}\left(A \cap B^{\prime} \cap E\right) \\
& +\mu^{*}\left(A^{\prime} \cap B^{\prime} \cap E\right) \\
\geq & \mu^{*}((A \cup B) \cap E)+\mu^{*}\left((A \cup B)^{\prime} \cap E\right),
\end{aligned}
$$

where we have used de Morgan and

$$
\mu^{*}(A \cap B \cap E)+\mu^{*}\left(A^{\prime} \cap B \cap E\right)+\mu^{*}\left(A \cap B^{\prime} \cap E\right) \geq \mu^{*}((A \cup B) \cap E)
$$

which follows from subadditivity and $(A \cup B) \cap E=(A \cap B \cap E) \cup\left(A^{\prime} \cap\right.$ $B \cap E) \cup\left(A \cap B^{\prime} \cap E\right)$. Since the reverse inequality is just subadditivity, we conclude that $\Sigma$ is an algebra.

Next, let $A_{n}$ be a sequence of sets from $\Sigma$. Without restriction we can assume that they are disjoint (compare the last argument in proof of Theorem A.3). Abbreviate $\tilde{A}_{n}=\bigcup_{k \leq n} A_{n}, A=\bigcup_{n} A_{n}$. Then for any set $E$ we have

$$
\begin{aligned}
\mu^{*}\left(\tilde{A}_{n} \cap E\right) & =\mu^{*}\left(A_{n} \cap \tilde{A}_{n} \cap E\right)+\mu^{*}\left(A_{n}^{\prime} \cap \tilde{A}_{n} \cap E\right) \\
& =\mu^{*}\left(A_{n} \cap E\right)+\mu^{*}\left(\tilde{A}_{n-1} \cap E\right) \\
& =\ldots=\sum_{k=1}^{n} \mu^{*}\left(A_{k} \cap E\right) .
\end{aligned}
$$

Using $\tilde{A}_{n} \in \Sigma$ and monotonicity of $\mu^{*}$, we infer

$$
\begin{aligned}
\mu^{*}(E) & =\mu^{*}\left(\tilde{A}_{n} \cap E\right)+\mu^{*}\left(\tilde{A}_{n}^{\prime} \cap E\right) \\
& \geq \sum_{k=1}^{n} \mu^{*}\left(A_{k} \cap E\right)+\mu^{*}\left(A^{\prime} \cap E\right) .
\end{aligned}
$$

Letting $n \rightarrow \infty$ and using subadditivity finally gives

$$
\begin{align*}
\mu^{*}(E) & \geq \sum_{k=1}^{\infty} \mu^{*}\left(A_{k} \cap E\right)+\mu^{*}\left(A^{\prime} \cap E\right) \\
& \geq \mu^{*}(A \cap E)+\mu^{*}\left(B^{\prime} \cap E\right) \geq \mu^{*}(E) \tag{A.7}
\end{align*}
$$

and we infer that $\Sigma$ is a $\sigma$-algebra.
Finally, setting $E=A$ in (A.7), we have

$$
\mu^{*}(A)=\sum_{k=1}^{\infty} \mu^{*}\left(A_{k} \cap A\right)+\mu^{*}\left(A^{\prime} \cap A\right)=\sum_{k=1}^{\infty} \mu^{*}\left(A_{k}\right)
$$

and we are done.
Remark: The constructed measure $\mu$ is complete; that is, for any measurable set $A$ of measure zero, any subset of $A$ is again measurable (Problem A.4).

The only remaining question is whether there are any nontrivial sets satisfying the Carathéodory condition.

Lemma A.8. Let $\mu$ be a premeasure on $\mathcal{A}$ and let $\mu^{*}$ be the associated outer measure. Then every set in $\mathcal{A}$ satisfies the Carathéodory condition.

Proof. Let $A_{n} \in \mathcal{A}$ be a countable cover for $E$. Then for any $A \in \mathcal{A}$ we have

$$
\sum_{n=1}^{\infty} \mu\left(A_{n}\right)=\sum_{n=1}^{\infty} \mu\left(A_{n} \cap A\right)+\sum_{n=1}^{\infty} \mu\left(A_{n} \cap A^{\prime}\right) \geq \mu^{*}(E \cap A)+\mu^{*}\left(E \cap A^{\prime}\right)
$$

since $A_{n} \cap A \in \mathcal{A}$ is a cover for $E \cap A$ and $A_{n} \cap A^{\prime} \in \mathcal{A}$ is a cover for $E \cap A^{\prime}$. Taking the infimum, we have $\mu^{*}(E) \geq \mu^{*}(E \cap A)+\mu^{*}\left(E \cap A^{\prime}\right)$, which finishes the proof.

Thus, as a consequence we obtain Theorem A.2.
Problem A.2. Show that $\mu^{*}$ defined in (A.5) is an outer measure. (Hint for the last property: Take a cover $\left\{B_{n k}\right\}_{k=1}^{\infty}$ for $A_{n}$ such that $\mu^{*}\left(A_{n}\right)=$ $\frac{\varepsilon}{2^{n}}+\sum_{k=1}^{\infty} \mu\left(B_{n k}\right)$ and note that $\left\{B_{n k}\right\}_{n, k=1}^{\infty}$ is a cover for $\bigcup_{n} A_{n}$.)
Problem A.3. Show that $\mu^{*}$ defined in (A.5) extends $\mu$. (Hint: For the cover $A_{n}$ it is no restriction to assume $A_{n} \cap A_{m}=\emptyset$ and $A_{n} \subseteq A$.)

Problem A.4. Show that the measure constructed in Theorem A. 7 is complete.

## A.3. Measurable functions

The Riemann integral works by splitting the $x$ coordinate into small intervals and approximating $f(x)$ on each interval by its minimum and maximum. The problem with this approach is that the difference between maximum and minimum will only tend to zero (as the intervals get smaller) if $f(x)$ is sufficiently nice. To avoid this problem, we can force the difference to go to zero by considering, instead of an interval, the set of $x$ for which $f(x)$ lies
between two given numbers $a<b$. Now we need the size of the set of these $x$, that is, the size of the preimage $f^{-1}((a, b))$. For this to work, preimages of intervals must be measurable.

A function $f: X \rightarrow \mathbb{R}^{n}$ is called measurable if $f^{-1}(A) \in \Sigma$ for every $A \in \mathfrak{B}^{n}$. A complex-valued function is called measurable if both its real and imaginary parts are. Clearly it suffices to check this condition for every set $A$ in a collection of sets which generate $\mathfrak{B}^{n}$, since the collection of sets for which it holds forms a $\sigma$-algebra by $f^{-1}\left(\mathbb{R}^{n} \backslash A\right)=X \backslash f^{-1}(A)$ and $f^{-1}\left(\bigcup_{j} A_{j}\right)=$ $\bigcup_{j} f^{-1}\left(A_{j}\right)$.
Lemma A.9. A function $f: X \rightarrow \mathbb{R}^{n}$ is measurable if and only if

$$
\begin{equation*}
f^{-1}(I) \in \Sigma \quad \forall I=\prod_{j=1}^{n}\left(a_{j}, \infty\right) . \tag{A.8}
\end{equation*}
$$

In particular, a function $f: X \rightarrow \mathbb{R}^{n}$ is measurable if and only if every component is measurable.

Proof. We need to show that $\mathfrak{B}$ is generated by rectangles of the above form. The $\sigma$-algebra generated by these rectangles also contains all open rectangles of the form $I=\prod_{j=1}^{n}\left(a_{j}, b_{j}\right)$. Moreover, given any open set $O$, we can cover it by such open rectangles satisfying $I \subseteq O$. By Lindelöf's theorem there is a countable subcover and hence every open set can be written as a countable union of open rectangles.

Clearly the intervals $\left(a_{j}, \infty\right)$ can also be replaced by $\left[a_{j}, \infty\right),\left(-\infty, a_{j}\right)$, or $\left(-\infty, a_{j}\right]$.

If $X$ is a topological space and $\Sigma$ the corresponding Borel $\sigma$-algebra, we will also call a measurable function a Borel function. Note that, in particular,

Lemma A.10. Let $X$ be a topological space and $\Sigma$ its Borel $\sigma$-algebra. Any continuous function is Borel. Moreover, if $f: X \rightarrow \mathbb{R}^{n}$ and $g: Y \subseteq \mathbb{R}^{n} \rightarrow$ $\mathbb{R}^{m}$ are Borel functions, then the composition $g \circ f$ is again Borel.

Sometimes it is also convenient to allow $\pm \infty$ as possible values for $f$, that is, functions $f: X \rightarrow \overline{\mathbb{R}}, \overline{\mathbb{R}}=\mathbb{R} \cup\{-\infty, \infty\}$. In this case $A \subseteq \overline{\mathbb{R}}$ is called Borel if $A \cap \mathbb{R}$ is.

The set of all measurable functions forms an algebra.
Lemma A.11. Let $X$ be a topological space and $\Sigma$ its Borel $\sigma$-algebra. Suppose $f, g: X \rightarrow \mathbb{R}$ are measurable functions. Then the sum $f+g$ and the product fg are measurable.

Proof. Note that addition and multiplication are continuous functions from $\mathbb{R}^{2} \rightarrow \mathbb{R}$ and hence the claim follows from the previous lemma.

Moreover, the set of all measurable functions is closed under all important limiting operations.
Lemma A.12. Suppose $f_{n}: X \rightarrow \mathbb{R}$ is a sequence of measurable functions. Then

$$
\begin{equation*}
\inf _{n \in \mathbb{N}} f_{n}, \quad \sup _{n \in \mathbb{N}} f_{n}, \quad \liminf _{n \rightarrow \infty} f_{n}, \quad \limsup _{n \rightarrow \infty} f_{n} \tag{A.9}
\end{equation*}
$$

are measurable as well.
Proof. It suffices to prove that $\sup f_{n}$ is measurable since the rest follows from $\inf f_{n}=-\sup \left(-f_{n}\right), \liminf f_{n}=\sup _{k} \inf _{n \geq k} f_{n}$, and $\limsup f_{n}=$ $\inf _{k} \sup _{n \geq k} f_{n}$. But $\left(\sup f_{n}\right)^{-1}((a, \infty))=\bigcup_{n} f_{n}^{-1}((a, \infty))$ and we are done.

A few immediate consequences are worthwhile noting: It follows that if $f$ and $g$ are measurable functions, so are $\min (f, g), \max (f, g),|f|=$ $\max (f,-f)$, and $f^{ \pm}=\max ( \pm f, 0)$. Furthermore, the pointwise limit of measurable functions is again measurable.

## A.4. The Lebesgue integral

Now we can define the integral for measurable functions as follows. A measurable function $s: X \rightarrow \mathbb{R}$ is called simple if its range is finite; that is, if

$$
\begin{equation*}
s=\sum_{j=1}^{p} \alpha_{j} \chi_{A_{j}}, \quad A_{j}=s^{-1}\left(\alpha_{j}\right) \in \Sigma . \tag{A.10}
\end{equation*}
$$

Here $\chi_{A}$ is the characteristic function of $A$; that is, $\chi_{A}(x)=1$ if $x \in A$ and $\chi_{A}(x)=0$ otherwise.

For a nonnegative simple function we define its integral as

$$
\begin{equation*}
\int_{A} s d \mu=\sum_{j=1}^{p} \alpha_{j} \mu\left(A_{j} \cap A\right) . \tag{A.11}
\end{equation*}
$$

Here we use the convention $0 \cdot \infty=0$.
Lemma A.13. The integral has the following properties:
(i) $\int_{A} s d \mu=\int_{X} \chi_{A} s d \mu$.
(ii) $\int_{\bigcup_{j=1}^{\infty} A_{j}} s d \mu=\sum_{j=1}^{\infty} \int_{A_{j}} s d \mu, \quad A_{j} \cap A_{k}=\emptyset$ for $j \neq k$.
(iii) $\int_{A} \alpha s d \mu=\alpha \int_{A} s d \mu, \alpha \geq 0$.
(iv) $\int_{A}(s+t) d \mu=\int_{A} s d \mu+\int_{A} t d \mu$.
(v) $A \subseteq B \Rightarrow \int_{A} s d \mu \leq \int_{B} s d \mu$.
(vi) $s \leq t \Rightarrow \int_{A} s d \mu \leq \int_{A} t d \mu$.

Proof. (i) is clear from the definition. (ii) follows from $\sigma$-additivity of $\mu$. (iii) is obvious. (iv) Let $s=\sum_{j} \alpha_{j} \chi_{A_{j}}, t=\sum_{j} \beta_{j} \chi_{B_{j}}$ and abbreviate $C_{j k}=\left(A_{j} \cap B_{k}\right) \cap A$. Then, by (ii),

$$
\begin{aligned}
\int_{A}(s+t) d \mu & =\sum_{j, k} \int_{C_{j k}}(s+t) d \mu=\sum_{j, k}\left(\alpha_{j}+\beta_{k}\right) \mu\left(C_{j k}\right) \\
& =\sum_{j, k}\left(\int_{C_{j k}} s d \mu+\int_{C_{j k}} t d \mu\right)=\int_{A} s d \mu+\int_{A} t d \mu .
\end{aligned}
$$

(v) follows from monotonicity of $\mu$. (vi) follows since by (iv) we can write $s=\sum_{j} \alpha_{j} \chi_{C_{j}}, t=\sum_{j} \beta_{j} \chi_{C_{j}}$ where, by assumption, $\alpha_{j} \leq \beta_{j}$.

Our next task is to extend this definition to arbitrary positive functions by

$$
\begin{equation*}
\int_{A} f d \mu=\sup _{s \leq f} \int_{A} s d \mu \tag{A.12}
\end{equation*}
$$

where the supremum is taken over all simple functions $s \leq f$. Note that, except for possibly (ii) and (iv), Lemma A. 13 still holds for this extension.

Theorem A. 14 (Monotone convergence). Let $f_{n}$ be a monotone nondecreasing sequence of nonnegative measurable functions, $f_{n} \nearrow f$. Then

$$
\begin{equation*}
\int_{A} f_{n} d \mu \rightarrow \int_{A} f d \mu \tag{A.13}
\end{equation*}
$$

Proof. By property (vi), $\int_{A} f_{n} d \mu$ is monotone and converges to some number $\alpha$. By $f_{n} \leq f$ and again (vi) we have

$$
\alpha \leq \int_{A} f d \mu
$$

To show the converse, let $s$ be simple such that $s \leq f$ and let $\theta \in(0,1)$. Put $A_{n}=\left\{x \in A \mid f_{n}(x) \geq \theta s(x)\right\}$ and note $A_{n} \nearrow A$ (show this). Then

$$
\int_{A} f_{n} d \mu \geq \int_{A_{n}} f_{n} d \mu \geq \theta \int_{A_{n}} s d \mu .
$$

Letting $n \rightarrow \infty$, we see

$$
\alpha \geq \theta \int_{A} s d \mu
$$

Since this is valid for any $\theta<1$, it still holds for $\theta=1$. Finally, since $s \leq f$ is arbitrary, the claim follows.

In particular

$$
\begin{equation*}
\int_{A} f d \mu=\lim _{n \rightarrow \infty} \int_{A} s_{n} d \mu \tag{A.14}
\end{equation*}
$$

for any monotone sequence $s_{n} \nearrow f$ of simple functions. Note that there is always such a sequence, for example,

$$
\begin{equation*}
s_{n}(x)=\sum_{k=0}^{2^{n}} \frac{k}{2^{n}} \chi_{f^{-1}\left(A_{k}\right)}(x), \quad A_{k}=\left[\frac{k}{2^{n}}, \frac{k+1}{2^{n}}\right), A_{2^{n}}=[n, \infty) \tag{A.15}
\end{equation*}
$$

By construction $s_{n}$ converges uniformly if $f$ is bounded, since $s_{n}(x)=n$ if $f(x)=\infty$ and $f(x)-s_{n}(x)<\frac{1}{n}$ if $f(x)<n+1$.

Now what about the missing items (ii) and (iv) from Lemma A.13? Since limits can be spread over sums, the extension is linear (i.e., item (iv) holds) and (ii) also follows directly from the monotone convergence theorem. We even have the following result:
Lemma A.15. If $f \geq 0$ is measurable, then $d \nu=f d \mu$ defined via

$$
\begin{equation*}
\nu(A)=\int_{A} f d \mu \tag{A.16}
\end{equation*}
$$

is a measure such that

$$
\begin{equation*}
\int g d \nu=\int g f d \mu \tag{A.17}
\end{equation*}
$$

Proof. As already mentioned, additivity of $\mu$ is equivalent to linearity of the integral and $\sigma$-additivity follows from the monotone convergence theorem:

$$
\nu\left(\bigcup_{n=1}^{\infty} A_{n}\right)=\int\left(\sum_{n=1}^{\infty} \chi_{A_{n}}\right) f d \mu=\sum_{n=1}^{\infty} \int \chi_{A_{n}} f d \mu=\sum_{n=1}^{\infty} \nu\left(A_{n}\right) .
$$

The second claim holds for simple functions and hence for all functions by construction of the integral.

If $f_{n}$ is not necessarily monotone, we have at least
Theorem A. 16 (Fatou's lemma). If $f_{n}$ is a sequence of nonnegative measurable function, then

$$
\begin{equation*}
\int_{A} \liminf _{n \rightarrow \infty} f_{n} d \mu \leq \liminf _{n \rightarrow \infty} \int_{A} f_{n} d \mu \tag{A.18}
\end{equation*}
$$

Proof. Set $g_{n}=\inf _{k \geq n} f_{k}$. Then $g_{n} \leq f_{n}$ implying

$$
\int_{A} g_{n} d \mu \leq \int_{A} f_{n} d \mu
$$

Now take the liminf on both sides and note that by the monotone convergence theorem

$$
\liminf _{n \rightarrow \infty} \int_{A} g_{n} d \mu=\lim _{n \rightarrow \infty} \int_{A} g_{n} d \mu=\int_{A} \lim _{n \rightarrow \infty} g_{n} d \mu=\int_{A} \liminf _{n \rightarrow \infty} f_{n} d \mu
$$

proving the claim.

If the integral is finite for both the positive and negative part $f^{ \pm}$of an arbitrary measurable function $f$, we call $f$ integrable and set

$$
\begin{equation*}
\int_{A} f d \mu=\int_{A} f^{+} d \mu-\int_{A} f^{-} d \mu . \tag{A.19}
\end{equation*}
$$

The set of all integrable functions is denoted by $\mathcal{L}^{1}(X, d \mu)$.
Lemma A.17. Lemma A. 13 holds for integrable functions $s, t$.
Similarly, we handle the case where $f$ is complex-valued by calling $f$ integrable if both the real and imaginary part are and setting

$$
\begin{equation*}
\int_{A} f d \mu=\int_{A} \operatorname{Re}(f) d \mu+\mathrm{i} \int_{A} \operatorname{Im}(f) d \mu \tag{A.20}
\end{equation*}
$$

Clearly $f$ is integrable if and only if $|f|$ is.
Lemma A.18. For any integrable functions $f, g$ we have

$$
\begin{equation*}
\left|\int_{A} f d \mu\right| \leq \int_{A}|f| d \mu \tag{A.21}
\end{equation*}
$$

and (triangle inequality)

$$
\begin{equation*}
\int_{A}|f+g| d \mu \leq \int_{A}|f| d \mu+\int_{A}|g| d \mu . \tag{A.22}
\end{equation*}
$$

Proof. Put $\alpha=\frac{z^{*}}{|z|}$, where $z=\int_{A} f d \mu$ (without restriction $z \neq 0$ ). Then

$$
\left|\int_{A} f d \mu\right|=\alpha \int_{A} f d \mu=\int_{A} \alpha f d \mu=\int_{A} \operatorname{Re}(\alpha f) d \mu \leq \int_{A}|f| d \mu,
$$

proving the first claim. The second follows from $|f+g| \leq|f|+|g|$.
In addition, our integral is well behaved with respect to limiting operations.

Theorem A. 19 (Dominated convergence). Let $f_{n}$ be a convergent sequence of measurable functions and set $f=\lim _{n \rightarrow \infty} f_{n}$. Suppose there is an integrable function $g$ such that $\left|f_{n}\right| \leq g$. Then $f$ is integrable and

$$
\begin{equation*}
\lim _{n \rightarrow \infty} \int f_{n} d \mu=\int f d \mu \tag{A.23}
\end{equation*}
$$

Proof. The real and imaginary parts satisfy the same assumptions and so do the positive and negative parts. Hence it suffices to prove the case where $f_{n}$ and $f$ are nonnegative.

By Fatou's lemma

$$
\liminf _{n \rightarrow \infty} \int_{A} f_{n} d \mu \geq \int_{A} f d \mu
$$

and

$$
\liminf _{n \rightarrow \infty} \int_{A}\left(g-f_{n}\right) d \mu \geq \int_{A}(g-f) d \mu
$$

Subtracting $\int_{A} g d \mu$ on both sides of the last inequality finishes the proof since $\lim \inf \left(-f_{n}\right)=-\limsup f_{n}$.

Remark: Since sets of measure zero do not contribute to the value of the integral, it clearly suffices if the requirements of the dominated convergence theorem are satisfied almost everywhere (with respect to $\mu$ ).

Note that the existence of $g$ is crucial, as the example $f_{n}(x)=\frac{1}{n} \chi_{[-n, n]}(x)$ on $\mathbb{R}$ with Lebesgue measure shows.
Example. If $\mu(x)=\sum_{n} \alpha_{n} \Theta\left(x-x_{n}\right)$ is a sum of Dirac measures, $\Theta(x)$ centered at $x=0$, then

$$
\begin{equation*}
\int f(x) d \mu(x)=\sum_{n} \alpha_{n} f\left(x_{n}\right) . \tag{A.24}
\end{equation*}
$$

Hence our integral contains sums as special cases.
Problem A.5. Show that the set $B(X)$ of bounded measurable functions with the sup norm is a Banach space. Show that the set $S(X)$ of simple functions is dense in $B(X)$. Show that the integral is a bounded linear functional on $B(X)$. (Hence Theorem 0.26 could be used to extend the integral from simple to bounded measurable functions.)

Problem A.6. Show that the dominated convergence theorem implies (under the same assumptions)

$$
\lim _{n \rightarrow \infty} \int\left|f_{n}-f\right| d \mu=0
$$

Problem A.7. Let $X \subseteq \mathbb{R}, Y$ be some measure space, and $f: X \times Y \rightarrow \mathbb{R}$. Suppose $y \mapsto f(x, y)$ is measurable for every $x$ and $x \mapsto f(x, y)$ is continuous for every $y$. Show that

$$
\begin{equation*}
F(x)=\int_{A} f(x, y) d \mu(y) \tag{A.25}
\end{equation*}
$$

is continuous if there is an integrable function $g(y)$ such that $|f(x, y)| \leq g(y)$.
Problem A.8. Let $X \subseteq \mathbb{R}, Y$ be some measure space, and $f: X \times Y \rightarrow \mathbb{R}$. Suppose $y \mapsto f(x, y)$ is measurable for all $x$ and $x \mapsto f(x, y)$ is differentiable for a.e. $y$. Show that

$$
\begin{equation*}
F(x)=\int_{A} f(x, y) d \mu(y) \tag{A.26}
\end{equation*}
$$

is differentiable if there is an integrable function $g(y)$ such that $\left|\frac{\partial}{\partial x} f(x, y)\right| \leq$ $g(y)$. Moreover, $x \mapsto \frac{\partial}{\partial x} f(x, y)$ is measurable and

$$
\begin{equation*}
F^{\prime}(x)=\int_{A} \frac{\partial}{\partial x} f(x, y) d \mu(y) \tag{A.27}
\end{equation*}
$$

in this case.

## A.5. Product measures

Let $\mu_{1}$ and $\mu_{2}$ be two measures on $\Sigma_{1}$ and $\Sigma_{2}$, respectively. Let $\Sigma_{1} \otimes \Sigma_{2}$ be the $\sigma$-algebra generated by rectangles of the form $A_{1} \times A_{2}$.
Example. Let $\mathfrak{B}$ be the Borel sets in $\mathbb{R}$. Then $\mathfrak{B}^{2}=\mathfrak{B} \otimes \mathfrak{B}$ are the Borel sets in $\mathbb{R}^{2}$ (since the rectangles are a basis for the product topology).

Any set in $\Sigma_{1} \otimes \Sigma_{2}$ has the section property; that is,
Lemma A.20. Suppose $A \in \Sigma_{1} \otimes \Sigma_{2}$. Then its sections

$$
\begin{equation*}
A_{1}\left(x_{2}\right)=\left\{x_{1} \mid\left(x_{1}, x_{2}\right) \in A\right\} \quad \text { and } \quad A_{2}\left(x_{1}\right)=\left\{x_{2} \mid\left(x_{1}, x_{2}\right) \in A\right\} \tag{A.28}
\end{equation*}
$$

are measurable.
Proof. Denote all sets $A \in \Sigma_{1} \otimes \Sigma_{2}$ with the property that $A_{1}\left(x_{2}\right) \in \Sigma_{1}$ by $S$. Clearly all rectangles are in $S$ and it suffices to show that $S$ is a $\sigma$-algebra. Now, if $A \in S$, then $\left(A^{\prime}\right)_{1}\left(x_{2}\right)=\left(A_{1}\left(x_{2}\right)\right)^{\prime} \in \Sigma_{2}$ and thus $S$ is closed under complements. Similarly, if $A_{n} \in S$, then $\left(\bigcup_{n} A_{n}\right)_{1}\left(x_{2}\right)=\bigcup_{n}\left(A_{n}\right)_{1}\left(x_{2}\right)$ shows that $S$ is closed under countable unions.

This implies that if $f$ is a measurable function on $X_{1} \times X_{2}$, then $f\left(., x_{2}\right)$ is measurable on $X_{1}$ for every $x_{2}$ and $f\left(x_{1},.\right)$ is measurable on $X_{2}$ for every $x_{1}$ (observe $A_{1}\left(x_{2}\right)=\left\{x_{1} \mid f\left(x_{1}, x_{2}\right) \in B\right\}$, where $A=\left\{\left(x_{1}, x_{2}\right) \mid f\left(x_{1}, x_{2}\right) \in B\right\}$ ).

Given two measures $\mu_{1}$ on $\Sigma_{1}$ and $\mu_{2}$ on $\Sigma_{2}$, we now want to construct the product measure $\mu_{1} \otimes \mu_{2}$ on $\Sigma_{1} \otimes \Sigma_{2}$ such that

$$
\begin{equation*}
\mu_{1} \otimes \mu_{2}\left(A_{1} \times A_{2}\right)=\mu_{1}\left(A_{1}\right) \mu_{2}\left(A_{2}\right), \quad A_{j} \in \Sigma_{j}, j=1,2 . \tag{A.29}
\end{equation*}
$$

Theorem A.21. Let $\mu_{1}$ and $\mu_{2}$ be two $\sigma$-finite measures on $\Sigma_{1}$ and $\Sigma_{2}$, respectively. Let $A \in \Sigma_{1} \otimes \Sigma_{2}$. Then $\mu_{2}\left(A_{2}\left(x_{1}\right)\right)$ and $\mu_{1}\left(A_{1}\left(x_{2}\right)\right)$ are measurable and

$$
\begin{equation*}
\int_{X_{1}} \mu_{2}\left(A_{2}\left(x_{1}\right)\right) d \mu_{1}\left(x_{1}\right)=\int_{X_{2}} \mu_{1}\left(A_{1}\left(x_{2}\right)\right) d \mu_{2}\left(x_{2}\right) . \tag{A.30}
\end{equation*}
$$

Proof. Let $S$ be the set of all subsets for which our claim holds. Note that $S$ contains at least all rectangles. It even contains the algebra of finite disjoint unions of rectangles. Thus it suffices to show that $S$ is a monotone class. If $\mu_{1}$ and $\mu_{2}$ are finite, measurability and equality of both integrals follow from the monotone convergence theorem for increasing sequences of
sets and from the dominated convergence theorem for decreasing sequences of sets.

If $\mu_{1}$ and $\mu_{2}$ are $\sigma$-finite, let $X_{i, j} \nearrow X_{i}$ with $\mu_{i}\left(X_{i, j}\right)<\infty$ for $i=1,2$. Now $\mu_{2}\left(\left(A \cap X_{1, j} \times X_{2, j}\right)_{2}\left(x_{1}\right)\right)=\mu_{2}\left(A_{2}\left(x_{1}\right) \cap X_{2, j}\right) \chi_{X_{1, j}}\left(x_{1}\right)$ and similarly with 1 and 2 exchanged. Hence by the finite case

$$
\begin{equation*}
\int_{X_{1}} \mu_{2}\left(A_{2} \cap X_{2, j}\right) \chi_{X_{1, j}} d \mu_{1}=\int_{X_{2}} \mu_{1}\left(A_{1} \cap X_{1, j}\right) \chi_{X_{2, j}} d \mu_{2} \tag{A.31}
\end{equation*}
$$

and the $\sigma$-finite case follows from the monotone convergence theorem.
Hence we can define

$$
\begin{equation*}
\mu_{1} \otimes \mu_{2}(A)=\int_{X_{1}} \mu_{2}\left(A_{2}\left(x_{1}\right)\right) d \mu_{1}\left(x_{1}\right)=\int_{X_{2}} \mu_{1}\left(A_{1}\left(x_{2}\right)\right) d \mu_{2}\left(x_{2}\right) \tag{A.32}
\end{equation*}
$$

or equivalently, since $\chi_{A_{1}\left(x_{2}\right)}\left(x_{1}\right)=\chi_{A_{2}\left(x_{1}\right)}\left(x_{2}\right)=\chi_{A}\left(x_{1}, x_{2}\right)$,

$$
\begin{align*}
\mu_{1} \otimes \mu_{2}(A) & =\int_{X_{1}}\left(\int_{X_{2}} \chi_{A}\left(x_{1}, x_{2}\right) d \mu_{2}\left(x_{2}\right)\right) d \mu_{1}\left(x_{1}\right) \\
& =\int_{X_{2}}\left(\int_{X_{1}} \chi_{A}\left(x_{1}, x_{2}\right) d \mu_{1}\left(x_{1}\right)\right) d \mu_{2}\left(x_{2}\right) . \tag{A.33}
\end{align*}
$$

Additivity of $\mu_{1} \otimes \mu_{2}$ follows from the monotone convergence theorem.
Note that (A.29) uniquely defines $\mu_{1} \otimes \mu_{2}$ as a $\sigma$-finite premeasure on the algebra of finite disjoint unions of rectangles. Hence by Theorem A. 5 it is the only measure on $\Sigma_{1} \otimes \Sigma_{2}$ satisfying (A.29).

Finally we have
Theorem A. 22 (Fubini). Let $f$ be a measurable function on $X_{1} \times X_{2}$ and let $\mu_{1}, \mu_{2}$ be $\sigma$-finite measures on $X_{1}, X_{2}$, respectively.
(i) If $f \geq 0$, then $\int f\left(., x_{2}\right) d \mu_{2}\left(x_{2}\right)$ and $\int f\left(x_{1},.\right) d \mu_{1}\left(x_{1}\right)$ are both measurable and

$$
\begin{align*}
& \iint f\left(x_{1}, x_{2}\right) d \mu_{1} \otimes \mu_{2}\left(x_{1}, x_{2}\right)=\int\left(\int f\left(x_{1}, x_{2}\right) d \mu_{1}\left(x_{1}\right)\right) d \mu_{2}\left(x_{2}\right) \\
& \quad=\int\left(\int f\left(x_{1}, x_{2}\right) d \mu_{2}\left(x_{2}\right)\right) d \mu_{1}\left(x_{1}\right) . \tag{A.34}
\end{align*}
$$

(ii) If $f$ is complex, then

$$
\begin{equation*}
\int\left|f\left(x_{1}, x_{2}\right)\right| d \mu_{1}\left(x_{1}\right) \in \mathcal{L}^{1}\left(X_{2}, d \mu_{2}\right) \tag{A.35}
\end{equation*}
$$

respectively,

$$
\begin{equation*}
\int\left|f\left(x_{1}, x_{2}\right)\right| d \mu_{2}\left(x_{2}\right) \in \mathcal{L}^{1}\left(X_{1}, d \mu_{1}\right) \tag{A.36}
\end{equation*}
$$

if and only if $f \in \mathcal{L}^{1}\left(X_{1} \times X_{2}, d \mu_{1} \otimes d \mu_{2}\right)$. In this case (A.34) holds.

Proof. By Theorem A. 21 and linearity the claim holds for simple functions. To see (i), let $s_{n} \nearrow f$ be a sequence of nonnegative simple functions. Then it follows by applying the monotone convergence theorem (twice for the double integrals).

For (ii) we can assume that $f$ is real-valued by considering its real and imaginary parts separately. Moreover, splitting $f=f^{+}-f^{-}$into its positive and negative parts, the claim reduces to (i).

In particular, if $f\left(x_{1}, x_{2}\right)$ is either nonnegative or integrable, then the order of integration can be interchanged.

Lemma A.23. If $\mu_{1}$ and $\mu_{2}$ are $\sigma$-finite regular Borel measures, then so is $\mu_{1} \otimes \mu_{2}$.

Proof. Regularity holds for every rectangle and hence also for the algebra of finite disjoint unions of rectangles. Thus the claim follows from Lemma A.6.

Note that we can iterate this procedure.
Lemma A.24. Suppose $\mu_{j}, j=1,2,3$, are $\sigma$-finite measures. Then

$$
\begin{equation*}
\left(\mu_{1} \otimes \mu_{2}\right) \otimes \mu_{3}=\mu_{1} \otimes\left(\mu_{2} \otimes \mu_{3}\right) \tag{A.37}
\end{equation*}
$$

Proof. First of all note that $\left(\Sigma_{1} \otimes \Sigma_{2}\right) \otimes \Sigma_{3}=\Sigma_{1} \otimes\left(\Sigma_{2} \otimes \Sigma_{3}\right)$ is the sigma algebra generated by the rectangles $A_{1} \times A_{2} \times A_{3}$ in $X_{1} \times X_{2} \times X_{3}$. Moreover, since

$$
\begin{aligned}
& \left(\left(\mu_{1} \otimes \mu_{2}\right) \otimes \mu_{3}\right)\left(A_{1} \times A_{2} \times A_{3}\right)=\mu_{1}\left(A_{1}\right) \mu_{2}\left(A_{2}\right) \mu_{3}\left(A_{3}\right) \\
& \quad=\left(\mu_{1} \otimes\left(\mu_{2} \otimes \mu_{3}\right)\right)\left(A_{1} \times A_{2} \times A_{3}\right),
\end{aligned}
$$

the two measures coincide on the algebra of finite disjoint unions of rectangles. Hence they coincide everywhere by Theorem A.5.

Example. If $\lambda$ is Lebesgue measure on $\mathbb{R}$, then $\lambda^{n}=\lambda \otimes \cdots \otimes \lambda$ is Lebesgue measure on $\mathbb{R}^{n}$. Since $\lambda$ is regular, so is $\lambda^{n}$.

Problem A.9. Show that the set of all finite union of rectangles $A_{1} \times A_{2}$ forms an algebra.
Problem A.10. Let $U \subseteq \mathbb{C}$ be a domain, $Y$ be some measure space, and $f: U \times Y \rightarrow \mathbb{R}$. Suppose $y \mapsto f(z, y)$ is measurable for every $z$ and $z \mapsto$ $f(z, y)$ is holomorphic for every $y$. Show that

$$
\begin{equation*}
F(z)=\int_{A} f(z, y) d \mu(y) \tag{A.38}
\end{equation*}
$$

is holomorphic if for every compact subset $V \subset U$ there is an integrable function $g(y)$ such that $|f(z, y)| \leq g(y), z \in V$. (Hint: Use Fubini and Morera.)

## A.6. Vague convergence of measures

Let $\mu_{n}$ be a sequence of Borel measures, we will say that $\mu_{n}$ converges to $\mu$ vaguely if

$$
\begin{equation*}
\int_{X} f d \mu_{n} \rightarrow \int_{X} f d \mu \tag{A.39}
\end{equation*}
$$

for every $f \in C_{c}(X)$.
We are only interested in the case of Borel measures on $\mathbb{R}$. In this case we have the following equivalent characterization of vague convergence.
Lemma A.25. Let $\mu_{n}$ be a sequence of Borel measures on $\mathbb{R}$. Then $\mu_{n} \rightarrow \mu$ vaguely if and only if the (normalized) distribution functions converge at every point of continuity of $\mu$.

Proof. Suppose $\mu_{n} \rightarrow \mu$ vaguely. Let $I$ be any bounded interval (closed, half closed, or open) with boundary points $x_{0}, x_{1}$. Moreover, choose continuous functions $f, g$ with compact support such that $f \leq \chi_{I} \leq g$. Then we have $\int f d \mu \leq \mu(I) \leq \int g d \mu$ and similarly for $\mu_{n}$. Hence

$$
\mu(I)-\mu_{n}(I) \leq \int g d \mu-\int f d \mu_{n} \leq \int(g-f) d \mu+\left|\int f d \mu-\int f d \mu_{n}\right|
$$

and

$$
\mu(I)-\mu_{n}(I) \geq \int f d \mu-\int g d \mu_{n} \geq \int(f-g) d \mu-\left|\int g d \mu-\int g d \mu_{n}\right|
$$

Combining both estimates, we see

$$
\left|\mu(I)-\mu_{n}(I)\right| \leq \int(g-f) d \mu+\left|\int f d \mu-\int f d \mu_{n}\right|+\left|\int g d \mu-\int g d \mu_{n}\right|
$$

and so

$$
\limsup _{n \rightarrow \infty}\left|\mu(I)-\mu_{n}(I)\right| \leq \int(g-f) d \mu
$$

Choosing $f, g$ such that $g-f \rightarrow \chi_{\left\{x_{0}\right\}}+\chi_{\left\{x_{1}\right\}}$ pointwise, we even get from dominated convergence that

$$
\limsup _{n \rightarrow \infty}\left|\mu(I)-\mu_{n}(I)\right| \leq \mu\left(\left\{x_{0}\right\}\right)+\mu\left(\left\{x_{1}\right\}\right)
$$

which proves that the distribution functions converge at every point of continuity of $\mu$.

Conversely, suppose that the distribution functions converge at every point of continuity of $\mu$. To see that in fact $\mu_{n} \rightarrow \mu$ vaguely, let $f \in C_{c}(\mathbb{R})$. Fix some $\varepsilon>0$ and note that, since $f$ is uniformly continuous, there is a
$\delta>0$ such that $|f(x)-f(y)| \leq \varepsilon$ whenever $|x-y| \leq \delta$. Next, choose some points $x_{0}<x_{1}<\cdots<x_{k}$ such that $\operatorname{supp}(f) \subset\left(x_{0}, x_{k}\right), \mu$ is continuous at $x_{j}$, and $x_{j}-x_{j-1} \leq \delta$ (recall that a monotone function has at most countable discontinuities). Furthermore, there is some $N$ such that $\left|\mu_{n}\left(x_{j}\right)-\mu\left(x_{j}\right)\right| \leq$ $\frac{\varepsilon}{2 k}$ for all $j$ and $n \geq N$. Then

$$
\begin{aligned}
\left|\int f d \mu_{n}-\int f d \mu\right| \leq & \sum_{j=1}^{k} \int_{\left(x_{j-1}, x_{j}\right]}\left|f(x)-f\left(x_{j}\right)\right| d \mu_{n}(x) \\
& +\sum_{j=1}^{k}\left|f\left(x_{j}\right)\right|\left|\mu\left(\left(x_{j-1}, x_{j}\right]\right)-\mu_{n}\left(\left(x_{j-1}, x_{j}\right]\right)\right| \\
& +\sum_{j=1}^{k} \int_{\left(x_{j-1}, x_{j}\right]}\left|f(x)-f\left(x_{j}\right)\right| d \mu(x) .
\end{aligned}
$$

Now, for $n \geq N$, the first and the last term on the right-hand side are both bounded by $\left(\mu\left(\left(x_{0}, x_{k}\right]\right)+\frac{\varepsilon}{k}\right) \varepsilon$ and the middle term is bounded by max $|f| \varepsilon$. Thus the claim follows.

Moreover, every bounded sequence of measures has a vaguely convergent subsequence.

Lemma A.26. Suppose $\mu_{n}$ is a sequence of finite Borel measures on $\mathbb{R}$ such that $\mu_{n}(\mathbb{R}) \leq M$. Then there exists a subsequence which converges vaguely to some measure $\mu$ with $\mu(\mathbb{R}) \leq M$.

Proof. Let $\mu_{n}(x)=\mu_{n}((-\infty, x])$ be the corresponding distribution functions. By $0 \leq \mu_{n}(x) \leq M$ there is a convergent subsequence for fixed $x$. Moreover, by the standard diagonal series trick, we can assume that $\mu_{n}(x)$ converges to some number $\mu(x)$ for each rational $x$. For irrational $x$ we set $\mu(x)=\inf _{x_{0}>x}\left\{\mu\left(x_{0}\right) \mid x_{0}\right.$ rational $\}$. Then $\mu(x)$ is monotone, $0 \leq \mu\left(x_{1}\right) \leq$ $\mu\left(x_{2}\right) \leq M$ for $x_{1} \leq x_{2}$. Furthermore,

$$
\mu(x-) \leq \liminf \mu_{n}(x) \leq \lim \sup \mu_{n}(x) \leq \mu(x)
$$

shows that $\mu_{n}(x) \rightarrow \mu(x)$ at every point of continuity of $\mu$. So we can redefine $\mu$ to be right continuous without changing this last fact.

In the case where the sequence is bounded, (A.39) even holds for a larger class of functions.

Lemma A.27. Suppose $\mu_{n} \rightarrow \mu$ vaguely and $\mu_{n}(\mathbb{R}) \leq M$. Then (A.39) holds for any $f \in C_{\infty}(\mathbb{R})$.

Proof. Split $f=f_{1}+f_{2}$, where $f_{1}$ has compact support and $\left|f_{2}\right| \leq \varepsilon$. Then $\left|\int f d \mu-\int f d \mu_{n}\right| \leq\left|\int f_{1} d \mu-\int f_{1} d \mu_{n}\right|+2 \varepsilon M$ and the claim follows.

Example. The example $d \mu_{n}(\lambda)=d \Theta(\lambda-n)$ shows that in the above claim $f$ cannot be replaced by a bounded continuous function. Moreover, the example $d \mu_{n}(\lambda)=n d \Theta(\lambda-n)$ also shows that the uniform bound cannot be dropped.

## A.7. Decomposition of measures

Let $\mu, \nu$ be two measures on a measure space $(X, \Sigma)$. They are called mutually singular (in symbols $\mu \perp \nu$ ) if they are supported on disjoint sets. That is, there is a measurable set $N$ such that $\mu(N)=0$ and $\nu(X \backslash N)=$ 0 .

Example. Let $\lambda$ be the Lebesgue measure and $\Theta$ the Dirac measure (centered at 0 ). Then $\lambda \perp \Theta$ : Just take $N=\{0\}$; then $\lambda(\{0\})=0$ and $\Theta(\mathbb{R} \backslash\{0\})=0$.

On the other hand, $\nu$ is called absolutely continuous with respect to $\mu($ in symbols $\nu \ll \mu)$ if $\mu(A)=0$ implies $\nu(A)=0$.
Example. The prototypical example is the measure $d \nu=f d \mu$ (compare Lemma A.15). Indeed $\mu(A)=0$ implies

$$
\begin{equation*}
\nu(A)=\int_{A} f d \mu=0 \tag{A.40}
\end{equation*}
$$

and shows that $\nu$ is absolutely continuous with respect to $\mu$. In fact, we will show below that every absolutely continuous measure is of this form. $\diamond$

The two main results will follow as simple consequence of the following result:

Theorem A.28. Let $\mu, \nu$ be $\sigma$-finite measures. Then there exists a unique (a.e.) nonnegative function $f$ and a set $N$ of $\mu$ measure zero, such that

$$
\begin{equation*}
\nu(A)=\nu(A \cap N)+\int_{A} f d \mu \tag{A.41}
\end{equation*}
$$

Proof. We first assume $\mu, \nu$ to be finite measures. Let $\alpha=\mu+\nu$ and consider the Hilbert space $L^{2}(X, d \alpha)$. Then

$$
\ell(h)=\int_{X} h d \nu
$$

is a bounded linear functional by Cauchy-Schwarz:

$$
\begin{aligned}
|\ell(h)|^{2} & =\left|\int_{X} 1 \cdot h d \nu\right|^{2} \leq\left(\int|1|^{2} d \nu\right)\left(\int|h|^{2} d \nu\right) \\
& \leq \nu(X)\left(\int|h|^{2} d \alpha\right)=\nu(X)\|h\|^{2} .
\end{aligned}
$$

Hence by the Riesz lemma (Theorem 1.8) there exists a $g \in L^{2}(X, d \alpha)$ such that

$$
\ell(h)=\int_{X} h g d \alpha .
$$

By construction

$$
\begin{equation*}
\nu(A)=\int \chi_{A} d \nu=\int \chi_{A} g d \alpha=\int_{A} g d \alpha . \tag{A.42}
\end{equation*}
$$

In particular, $g$ must be positive a.e. (take $A$ the set where $g$ is negative). Furthermore, let $N=\{x \mid g(x) \geq 1\}$. Then

$$
\nu(N)=\int_{N} g d \alpha \geq \alpha(N)=\mu(N)+\nu(N)
$$

which shows $\mu(N)=0$. Now set

$$
f=\frac{g}{1-g} \chi_{N^{\prime}}, \quad N^{\prime}=X \backslash N .
$$

Then, since (A.42) implies $d \nu=g d \alpha$, respectively, $d \mu=(1-g) d \alpha$, we have

$$
\int_{A} f d \mu=\int \chi_{A} \frac{g}{1-g} \chi_{N^{\prime}} d \mu=\int \chi_{A \cap N^{\prime}} g d \alpha=\nu\left(A \cap N^{\prime}\right)
$$

as desired. Clearly $f$ is unique, since if there is a second function $\tilde{f}$, then $\int_{A}(f-\tilde{f}) d \mu=0$ for every $A$ shows $f-\tilde{f}=0$ a.e.

To see the $\sigma$-finite case, observe that $X_{n} \nearrow X, \mu\left(X_{n}\right)<\infty$ and $Y_{n} \nearrow X$, $\nu\left(Y_{n}\right)<\infty$ implies $X_{n} \cap Y_{n} \nearrow X$ and $\alpha\left(X_{n} \cap Y_{n}\right)<\infty$. Hence when restricted to $X_{n} \cap Y_{n}$, we have sets $N_{n}$ and functions $f_{n}$. Now take $N=\bigcup N_{n}$ and choose $f$ such that $\left.f\right|_{X_{n}}=f_{n}$ (this is possible since $\left.f_{n+1}\right|_{X_{n}}=f_{n}$ a.e.). Then $\mu(N)=0$ and

$$
\nu\left(A \cap N^{\prime}\right)=\lim _{n \rightarrow \infty} \nu\left(A \cap\left(X_{n} \backslash N\right)\right)=\lim _{n \rightarrow \infty} \int_{A \cap X_{n}} f d \mu=\int_{A} f d \mu,
$$

which finishes the proof.
Now the anticipated results follow with no effort:
Theorem A. 29 (Lebesgue decomposition). Let $\mu, \nu$ be two $\sigma$-finite measures on a measure space $(X, \Sigma)$. Then $\nu$ can be uniquely decomposed as $\nu=\nu_{a c}+\nu_{\text {sing }}$, where $\nu_{a c}$ and $\nu_{\text {sing }}$ are mutually singular and $\nu_{a c}$ is absolutely continuous with respect to $\mu$.

Proof. Taking $\nu_{\text {sing }}(A)=\nu(A \cap N)$ and $d \nu_{a c}=f d \mu$, there is at least one such decomposition. To show uniqueness, first let $\nu$ be finite. If there is another one, $\nu=\tilde{\nu}_{\text {ac }}+\tilde{\nu}_{\text {sing }}$, then let $\tilde{N}$ be such that $\mu(\tilde{N})=0$ and $\tilde{\nu}_{\text {sing }}\left(\tilde{N}^{\prime}\right)=0$. Then $\tilde{\nu}_{\text {sing }}(A)-\tilde{\nu}_{\text {sing }}(A)=\int_{A}(\tilde{f}-f) d \mu$. In particular, $\int_{A \cap N^{\prime} \cap \tilde{N}^{\prime}}(\tilde{f}-f) d \mu=0$ and hence $\tilde{f}=f$ a.e. away from $N \cup \tilde{N}$. Since
$\mu(N \cup \tilde{N})=0$, we have $\tilde{f}=f$ a.e. and hence $\tilde{\nu}_{a c}=\nu_{a c}$ as well as $\tilde{\nu}_{\text {sing }}=$ $\nu-\tilde{\nu}_{a c}=\nu-\nu_{a c}=\nu_{s i n g}$. The $\sigma$-finite case follows as usual.

Theorem A. 30 (Radon-Nikodym). Let $\mu, \nu$ be two $\sigma$-finite measures on a measure space $(X, \Sigma)$. Then $\nu$ is absolutely continuous with respect to $\mu$ if and only if there is a positive measurable function $f$ such that

$$
\begin{equation*}
\nu(A)=\int_{A} f d \mu \tag{A.43}
\end{equation*}
$$

for every $A \in \Sigma$. The function $f$ is determined uniquely a.e. with respect to $\mu$ and is called the Radon-Nikodym derivative $\frac{d \nu}{d \mu}$ of $\nu$ with respect to $\mu$.

Proof. Just observe that in this case $\nu(A \cap N)=0$ for every $A$; that is, $\nu_{\text {sing }}=0$.

Problem A.11. Let $\mu$ be a Borel measure on $\mathfrak{B}$ and suppose its distribution function $\mu(x)$ is differentiable. Show that the Radon-Nikodym derivative equals the ordinary derivative $\mu^{\prime}(x)$.

Problem A.12. Suppose $\mu$ and $\nu$ are inner regular measures. Show that $\nu \ll \mu$ if and only if $\mu(C)=0$ implies $\nu(C)=0$ for every compact set.

Problem A.13. Let $d \nu=f d \mu$. Suppose $f>0$ a.e. with respect to $\mu$. Then $\mu \ll \nu$ and $d \mu=f^{-1} d \nu$.

Problem A. 14 (Chain rule). Show that $\nu \ll \mu$ is a transitive relation. In particular, if $\omega \ll \nu \ll \mu$, show that

$$
\frac{d \omega}{d \mu}=\frac{d \omega}{d \nu} \frac{d \nu}{d \mu} .
$$

Problem A.15. Suppose $\nu \ll \mu$. Show that for any measure $\omega$ we have

$$
\frac{d \omega}{d \mu} d \mu=\frac{d \omega}{d \nu} d \nu+d \zeta
$$

where $\zeta$ is a positive measure (depending on $\omega$ ) which is singular with respect to $\nu$. Show that $\zeta=0$ if and only if $\mu \ll \nu$.

## A.8. Derivatives of measures

If $\mu$ is a Borel measure on $\mathfrak{B}$ and its distribution function $\mu(x)$ is differentiable, then the Radon-Nikodym derivative is just the ordinary derivative $\mu^{\prime}(x)$ (Problem A.11). Our aim in this section is to generalize this result to arbitrary regular Borel measures on $\mathfrak{B}^{n}$.

We call

$$
\begin{equation*}
(D \mu)(x)=\lim _{\varepsilon \downarrow 0} \frac{\mu\left(B_{\varepsilon}(x)\right)}{\left|B_{\varepsilon}(x)\right|} \tag{A.44}
\end{equation*}
$$

the derivative of $\mu$ at $x \in \mathbb{R}^{n}$ provided the above limit exists. (Here $B_{r}(x) \subset$ $\mathbb{R}^{n}$ is a ball of radius $r$ centered at $x \in \mathbb{R}^{n}$ and $|A|$ denotes the Lebesgue measure of $A \in \mathfrak{B}^{n}$.)

Note that for a Borel measure on $\mathfrak{B},(D \mu)(x)$ exists if and only if $\mu(x)$ (as defined in (A.3)) is differentiable at $x$ and $(D \mu)(x)=\mu^{\prime}(x)$ in this case.

To compute the derivative of $\mu$, we introduce the upper and lower derivative,

$$
\begin{equation*}
(\bar{D} \mu)(x)=\limsup _{\varepsilon \downarrow 0} \frac{\mu\left(B_{\varepsilon}(x)\right)}{\left|B_{\varepsilon}(x)\right|} \quad \text { and } \quad(\underline{D} \mu)(x)=\liminf _{\varepsilon \downarrow 0} \frac{\mu\left(B_{\varepsilon}(x)\right)}{\left|B_{\varepsilon}(x)\right|} . \tag{A.45}
\end{equation*}
$$

Clearly $\mu$ is differentiable if $(\bar{D} \mu)(x)=(\underline{D} \mu)(x)<\infty$. First of all note that they are measurable:

Lemma A.31. The upper derivative is lower semicontinuous; that is, the set $\{x \mid(\bar{D} \mu)(x)>\alpha\}$ is open for every $\alpha \in \mathbb{R}$. Similarly, the lower derivative is upper semicontinuous; that is, $\{x \mid(\bar{D} \mu)(x)<\alpha\}$ is open.

Proof. We only prove the claim for $\bar{D} \mu$, the case $\underline{D} \mu$ being similar. Abbreviate

$$
M_{r}(x)=\sup _{0<\varepsilon<r} \frac{\mu\left(B_{\varepsilon}(x)\right)}{\left|B_{\varepsilon}(x)\right|}
$$

and note that it suffices to show that $O_{r}=\left\{x \mid M_{r}(x)>\alpha\right\}$ is open.
If $x \in O_{r}$, there is some $\varepsilon<r$ such that

$$
\frac{\mu\left(B_{\varepsilon}(x)\right)}{\left|B_{\varepsilon}(x)\right|}>\alpha .
$$

Let $\delta>0$ and $y \in B_{\delta}(x)$. Then $B_{\varepsilon}(x) \subseteq B_{\varepsilon+\delta}(y)$ implying

$$
\frac{\mu\left(B_{\varepsilon+\delta}(y)\right)}{\left|B_{\varepsilon+\delta}(y)\right|} \geq\left(\frac{\varepsilon}{\varepsilon+\delta}\right)^{n} \frac{\mu\left(B_{\varepsilon}(x)\right)}{\left|B_{\varepsilon}(x)\right|}>\alpha
$$

for $\delta$ sufficiently small. That is, $B_{\delta}(x) \subseteq O$.
In particular, both the upper and lower derivatives are measurable. Next, the following geometric fact of $\mathbb{R}^{n}$ will be needed.

Lemma A.32. Given open balls $B_{1}, \ldots, B_{m}$ in $\mathbb{R}^{n}$, there is a subset of disjoint balls $B_{j_{1}}, \ldots, B_{j_{k}}$ such that

$$
\begin{equation*}
\left|\bigcup_{i=1}^{m} B_{i}\right| \leq 3^{n} \sum_{i=1}^{k}\left|B_{j_{i}}\right| . \tag{A.46}
\end{equation*}
$$

Proof. Assume that the balls $B_{j}$ are ordered by radius. Start with $B_{j_{1}}=$ $B_{1}=B_{r_{1}}\left(x_{1}\right)$ and remove all balls from our list which intersect $B_{j_{1}}$. Observe
that the removed balls are all contained in $3 B_{1}=B_{3 r_{1}}\left(x_{1}\right)$. Proceeding like this, we obtain $B_{j_{1}}, \ldots, B_{j_{k}}$ such that

$$
\bigcup_{i=1}^{m} B_{i} \subseteq \bigcup_{i=1}^{k} 3 B_{r_{j_{i}}}
$$

and the claim follows since $|3 B|=3^{n}|B|$.
Now we can show
Lemma A.33. Let $\alpha>0$. For any Borel set $A$ we have

$$
\begin{equation*}
|\{x \in A \mid(\bar{D} \mu)(x)>\alpha\}| \leq 3^{n} \frac{\mu(A)}{\alpha} \tag{А.47}
\end{equation*}
$$

and

$$
\begin{equation*}
|\{x \in A \mid(\bar{D} \mu)(x)>0\}|=0, \text { whenever } \mu(A)=0 \tag{A.48}
\end{equation*}
$$

Proof. Let $A_{\alpha}=\{x \in A \mid(\bar{D} \mu)(x)>\alpha\}$. We will show

$$
|K| \leq 3^{n} \frac{\mu(O)}{\alpha}
$$

for any compact set $K$ and open set $O$ with $K \subseteq A_{\alpha} \subseteq O$. The first claim then follows from regularity of $\mu$ and the Lebesgue measure.

Given fixed $K, O$, for every $x \in K$ there is some $r_{x}$ such that $B_{r_{x}}(x) \subseteq O$ and $\left|B_{r_{x}}(x)\right|<\alpha^{-1} \mu\left(B_{r_{x}}(x)\right)$. Since $K$ is compact, we can choose a finite subcover of $K$. Moreover, by Lemma A. 32 we can refine our set of balls such that

$$
|K| \leq 3^{n} \sum_{i=1}^{k}\left|B_{r_{i}}\left(x_{i}\right)\right|<\frac{3^{n}}{\alpha} \sum_{i=1}^{k} \mu\left(B_{r_{i}}\left(x_{i}\right)\right) \leq 3^{n} \frac{\mu(O)}{\alpha} .
$$

To see the second claim, observe that

$$
\{x \in A \mid(\bar{D} \mu)(x)>0\}=\bigcup_{j=1}^{\infty}\left\{x \in A \left\lvert\,(\bar{D} \mu)(x)>\frac{1}{j}\right.\right\}
$$

and by the first part $\left|\left\{x \in A \left\lvert\,(\bar{D} \mu)(x)>\frac{1}{j}\right.\right\}\right|=0$ for any $j$ if $\mu(A)=0$.
Theorem A. 34 (Lebesgue). Let $f$ be (locally) integrable, then for a.e. $x \in$ $\mathbb{R}^{n}$ we have

$$
\begin{equation*}
\lim _{r \downarrow 0} \frac{1}{\left|B_{r}(x)\right|} \int_{B_{r}(x)}|f(y)-f(x)| d y=0 . \tag{A.49}
\end{equation*}
$$

Proof. Decompose $f$ as $f=g+h$, where $g$ is continuous and $\|h\|_{1}<\varepsilon$ (Theorem 0.34) and abbreviate

$$
D_{r}(f)(x)=\frac{1}{\left|B_{r}(x)\right|} \int_{B_{r}(x)}|f(y)-f(x)| d y .
$$

Then, since $\lim D_{r}(g)(x)=0($ for every $x)$ and $D_{r}(f) \leq D_{r}(g)+D_{r}(h)$, we have

$$
\underset{r \downarrow 0}{\limsup } D_{r}(f)(x) \leq \underset{r \downarrow 0}{\limsup } D_{r}(h)(x) \leq(\bar{D} \mu)(x)+|h(x)|,
$$

where $d \mu=|h| d x$. This implies

$$
\left\{x \mid \limsup _{r \downarrow 0} D_{r}(f)(x) \geq 2 \alpha\right\} \subseteq\{x \mid(\bar{D} \mu)(x) \geq \alpha\} \cup\{x||h(x)| \geq \alpha\}
$$

and using the first part of Lemma A. 33 plus $\left|\left\{x||h(x)| \geq \alpha\} \mid \leq \alpha^{-1}\|h\|_{1}\right.\right.$, we see

$$
\left|\left\{x \mid \limsup _{r \downarrow 0} D_{r}(f)(x) \geq 2 \alpha\right\}\right| \leq\left(3^{n}+1\right) \frac{\varepsilon}{\alpha} .
$$

Since $\varepsilon$ is arbitrary, the Lebesgue measure of this set must be zero for every $\alpha$. That is, the set where the limsup is positive has Lebesgue measure zero.

The points where (A.49) holds are called Lebesgue points of $f$.
Note that the balls can be replaced by more general sets: A sequence of sets $A_{j}(x)$ is said to shrink to $x$ nicely if there are balls $B_{r_{j}}(x)$ with $r_{j} \rightarrow 0$ and a constant $\varepsilon>0$ such that $A_{j}(x) \subseteq B_{r_{j}}(x)$ and $\left|A_{j}\right| \geq \varepsilon\left|B_{r_{j}}(x)\right|$. For example $A_{j}(x)$ could be some balls or cubes (not necessarily containing $x$ ). However, the portion of $B_{r_{j}}(x)$ which they occupy must not go to zero! For example the rectangles $\left(0, \frac{1}{j}\right) \times\left(0, \frac{2}{j}\right) \subset \mathbb{R}^{2}$ do shrink nicely to 0 , but the rectangles $\left(0, \frac{1}{j}\right) \times\left(0, \frac{2}{j^{2}}\right)$ do not.

Lemma A.35. Let $f$ be (locally) integrable. Then at every Lebesgue point we have

$$
\begin{equation*}
f(x)=\lim _{j \rightarrow \infty} \frac{1}{\left|A_{j}(x)\right|} \int_{A_{j}(x)} f(y) d y \tag{A.50}
\end{equation*}
$$

whenever $A_{j}(x)$ shrinks to $x$ nicely.
Proof. Let $x$ be a Lebesgue point and choose some nicely shrinking sets $A_{j}(x)$ with corresponding $B_{r_{j}}(x)$ and $\varepsilon$. Then

$$
\frac{1}{\left|A_{j}(x)\right|} \int_{A_{j}(x)}|f(y)-f(x)| d y \leq \frac{1}{\varepsilon\left|B_{r_{j}}(x)\right|} \int_{B_{r_{j}}(x)}|f(y)-f(x)| d y
$$

and the claim follows.
Corollary A.36. Suppose $\mu$ is an absolutely continuous Borel measure on $\mathbb{R}$. Then its distribution function is differentiable a.e. and $d \mu(x)=\mu^{\prime}(x) d x$.

As another consequence we obtain

Theorem A.37. Let $\mu$ be a Borel measure on $\mathbb{R}^{n}$. The derivative $D \mu$ exists a.e. with respect to Lebesgue measure and equals the Radon-Nikodym derivative of the absolutely continuous part of $\mu$ with respect to Lebesgue measure; that is,

$$
\begin{equation*}
\mu_{a c}(A)=\int_{A}(D \mu)(x) d x . \tag{A.51}
\end{equation*}
$$

Proof. If $d \mu=f d x$ is absolutely continuous with respect to Lebesgue measure, the claim follows from Theorem A.34. To see the general case, use the Lebesgue decomposition of $\mu$ and let $N$ be a support for the singular part with $|N|=0$. Then $\left(\bar{D} \mu_{\text {sing }}\right)(x)=0$ for a.e. $x \in \mathbb{R}^{n} \backslash N$ by the second part of Lemma A.33.

In particular, $\mu$ is singular with respect to Lebesgue measure if and only if $D \mu=0$ a.e. with respect to Lebesgue measure.

Using the upper and lower derivatives, we can also give supports for the absolutely and singularly continuous parts.

Theorem A.38. The set $\{x \mid(D \mu)(x)=\infty\}$ is a support for the singular and $\{x \mid 0<(D \mu)(x)<\infty\}$ is a support for the absolutely continuous part.

Proof. First suppose $\mu$ is purely singular. Let us show that the set $O_{k}=$ $\{x \mid(\underline{D} \mu)(x)<k\}$ satisfies $\mu\left(O_{k}\right)=0$ for every $k \in \mathbb{N}$.

Let $K \subset O_{k}$ be compact, and let $V_{j} \supset K$ be some open set such that $\left|V_{j} \backslash K\right| \leq \frac{1}{j}$. For every $x \in K$ there is some $\varepsilon=\varepsilon(x)$ such that $B_{\varepsilon}(x) \subseteq V_{j}$ and $\mu\left(B_{\varepsilon}(x)\right) \leq k\left|B_{\varepsilon}(x)\right|$. By compactness, finitely many of these balls cover $K$ and hence

$$
\mu(K) \leq \sum_{i} \mu\left(B_{\varepsilon_{i}}\left(x_{i}\right)\right) \leq k \sum_{i}\left|B_{\varepsilon_{i}}\left(x_{i}\right)\right| .
$$

Selecting disjoint balls as in Lemma A. 32 further shows

$$
\mu(K) \leq k 3^{n} \sum_{\ell}\left|B_{\varepsilon_{i_{\ell}}}\left(x_{i_{\ell}}\right)\right| \leq k 3^{n}\left|V_{j}\right| .
$$

Letting $j \rightarrow \infty$, we see $\mu(K) \leq k 3^{n}|K|$ and by regularity we even have $\mu(A) \leq k 3^{n}|A|$ for every $A \subseteq O_{k}$. Hence $\mu$ is absolutely continuous on $O_{k}$ and since we assumed $\mu$ to be singular, we must have $\mu\left(O_{k}\right)=0$.

Thus $\left(\underline{D} \mu_{\text {sing }}\right)(x)=\infty$ for a.e. $x$ with respect to $\mu_{\text {sing }}$ and we are done.

Finally, we note that these supports are minimal. Here a support $M$ of some measure $\mu$ is called a minimal support (it is sometimes also called an essential support) if any subset $M_{0} \subseteq M$ which does not support $\mu$ (i.e., $\mu\left(M_{0}\right)=0$ ) has Lebesgue measure zero.

Lemma A.39. The set $M_{a c}=\{x \mid 0<(D \mu)(x)<\infty\}$ is a minimal support for $\mu_{a c}$.

Proof. Suppose $M_{0} \subseteq M_{a c}$ and $\mu_{a c}\left(M_{0}\right)=0$. Set $M_{\varepsilon}=\left\{x \in M_{0} \mid \varepsilon<\right.$ $(D \mu)(x)\}$ for $\varepsilon>0$. Then $M_{\varepsilon} \nearrow M_{0}$ and

$$
\left|M_{\varepsilon}\right|=\int_{M_{\varepsilon}} d x \leq \frac{1}{\varepsilon} \int_{M_{\varepsilon}}(D \mu)(x) d x=\frac{1}{\varepsilon} \mu_{a c}\left(M_{\varepsilon}\right) \leq \frac{1}{\varepsilon} \mu_{a c}\left(M_{0}\right)=0
$$

shows $\left|M_{0}\right|=\lim _{\varepsilon \downarrow 0}\left|M_{\varepsilon}\right|=0$.
Note that the set $M=\{x \mid 0<(D \mu)(x)\}$ is a minimal support of $\mu$.
Example. The Cantor function is constructed as follows: Take the sets $C_{n}$ used in the construction of the Cantor set $C: C_{n}$ is the union of $2^{n}$ closed intervals with $2^{n}-1$ open gaps in between. Set $f_{n}$ equal to $j / 2^{n}$ on the $j$ 'th gap of $C_{n}$ and extend it to $[0,1]$ by linear interpolation. Note that, since we are creating precisely one new gap between every old gap when going from $C_{n}$ to $C_{n+1}$, the value of $f_{n+1}$ is the same as the value of $f_{n}$ on the gaps of $C_{n}$. In particular, $\left\|f_{n}-f_{m}\right\|_{\infty} \leq 2^{-\min (n, m)}$ and hence we can define the Cantor function as $f=\lim _{n \rightarrow \infty} f_{n}$. By construction $f$ is a continuous function which is constant on every subinterval of $[0,1] \backslash C$. Since $C$ is of Lebesgue measure zero, this set is of full Lebesgue measure and hence $f^{\prime}=0$ a.e. in $[0,1]$. In particular, the corresponding measure, the Cantor measure, is supported on $C$ and is purely singular with respect to Lebesgue measure.

Problem A.16. Show that $M=\{x \mid 0<(D \mu)(x)\}$ is a minimal support of $\mu$.

## Bibliographical notes

The aim of this section is not to give a comprehensive guide to the literature, but to document the sources from which I have learned the materials and which I have used during the preparation of this text. In addition, I will point out some standard references for further reading. In some sense all books on this topic are inspired by von Neumann's celebrated monograph [64] and the present text is no exception.

General references for the first part are Akhiezer and Glazman [2], Berthier (Boutet de Monvel) [9], Blank, Exner, and Havlíček [10], Edmunds and Evans [16], Lax [25], Reed and Simon [40], Weidmann [60], [62], or Yosida [66].
Chapter 0: A first look at Banach and Hilbert spaces
As a reference for general background I can warmly recommend Kelly's classical book [26]. The rest is standard material and can be found in any book on functional analysis.

## Chapter 1: Hilbert spaces

The material in this chapter is again classical and can be found in any book on functional analysis. I mainly follow Reed and Simon [40], respectively, Weidmann [60], with the main difference being that I use orthonormal sets and their projections as the central theme from which everything else is derived. For an alternate problem based approach see Halmos' book [22].
Chapter 2: Self-adjointness and spectrum
This chapter is still similar in spirit to [40], [60] with some ideas taken from Schechter [48].

## Chapter 3: The spectral theorem

The approach via the Herglotz representation theorem follows Weidmann [60]. However, I use projection-valued measures as in Reed and Simon [40] rather than the resolution of the identity. Moreover, I have augmented the discussion by adding material on spectral types and the connections with the boundary values of the resolvent. For a survey containing several recent results see [28].
Chapter 4: Applications of the spectral theorem
This chapter collects several applications from various sources which I have found useful or which are needed later on. Again Reed and Simon [40] and Weidmann [60], [63] are the main references here.

## Chapter 5: Quantum dynamics

The material is a synthesis of the lecture notes by $\operatorname{Enß}[\mathbf{1 8}]$, Reed and Simon [40], [42], and Weidmann [63].

## Chapter 6: Perturbation theory for self-adjoint operators

This chapter is similar to [60] (which contains more results) with the main difference that I have added some material on quadratic forms. In particular, the section on quadratic forms contains, in addition to the classical results, some material which I consider useful but was unable to find (at least not in the present form) in the literature. The prime reference here is Kato's monumental treatise [24] and Simon's book [49]. For further information on trace class operators see Simon's classic [52]. The idea to extend the usual notion of strong resolvent convergence by allowing the approximating operators to live on subspaces is taken from Weidmann [62].
Chapter 7: The free Schrödinger operator
Most of the material is classical. Much more on the Fourier transform can be found in Reed and Simon [41].
Chapter 8: Algebraic methods
This chapter collects some material which can be found in almost any physics text book on quantum mechanics. My only contribution is to provide some mathematical details. I recommend the classical book by Thirring [58] and the visual guides by Thaller [56], [57].
Chapter 9: One-dimensional Schrödinger operators
One-dimensional models have always played a central role in understanding quantum mechanical phenomena. In particular, general wisdom used to say that Schrödinger operators should have absolutely continuous spectrum plus some discrete point spectrum, while singular continuous spectrum is a pathology that should not occur in examples with bounded $V$ [14, Sect. 10.4].

In fact, a large part of [43] is devoted to establishing the absence of singular continuous spectrum. This was proven wrong by Pearson, who constructed an explicit one-dimensional example with singular continuous spectrum. Moreover, after the appearance of random models, it became clear that such kind of exotic spectra (singular continuous or dense pure point) are frequently generic. The starting point is often the boundary behaviour of the Weyl $m$-function and its connection with the growth properties of solutions of the underlying differential equation, the latter being known as Gilbert and Pearson or subordinacy theory. One of my main goals is to give a modern introduction to this theory. The section on inverse spectral theory presents a simple proof for the Borg-Marchenko theorem (in the local version of Simon) from Bennewitz [8]. Again this result is the starting point of almost all other inverse spectral results for Sturm-Liouville equations and should enable the reader to start reading research papers in this area.

Other references with further information are the lecture notes by Weidmann [61] or the classical books by Coddington and Levinson [13], Levitan [29], Levitan and Sargsjan [30], [31], Marchenko [33], Naimark [34], Pearson [37]. See also the recent monographs by Rofe-Betekov and Kholkin [46], Zettl $[\mathbf{6 7}]$ or the recent collection of historic and survey articles [4]. For a nice introduction to random models I can recommend the recent notes by Kirsch $[\mathbf{2 7}]$ or the classical monographs by Carmona and Lacroix [11] or Pastur and Figotin [36]. For the discrete analog of Sturm-Liouville operators, Jacobi operators, see my monograph [54].
Chapter 10: One-particle Schrödinger operators
The presentation in the first two sections is influenced by Enß [18] and Thirring [58]. The solution of the Schrödinger equation in spherical coordinates can be found in any text book on quantum mechanics. Again I tried to provide some missing mathematical details. Several other explicitly solvable examples can be found in the books by Albeverio et al. [3] or Flügge [19]. For the formulation of quantum mechanics via path integrals I suggest Roepstorff [45] or Simon [50].
Chapter 11: Atomic Schrödinger operators
This chapter essentially follows Cycon, Froese, Kirsch, and Simon [14]. For a recent review see Simon [51].

## Chapter 12: Scattering theory

This chapter follows the lecture notes by Enß [18] (see also [17]) using some material from Perry [38]. Further information on mathematical scattering theory can be found in Amrein, Jauch, and Sinha [5], Baumgaertel and Wollenberg [6], Chadan and Sabatier [12], Cycon, Froese, Kirsch, and Simon [14], Newton [35], Pearson [37], Reed and Simon [42], or Yafaev [65].

## Appendix A: Almost everything about Lebesgue integration

Most parts follow Rudin's book [47], respectively, Bauer [7], with some ideas also taken from Weidmann [60]. I have tried to strip everything down to the results needed here while staying self-contained. Another useful reference is the book by Lieb and Loss [32].

## Glossary of notation

| $A C(I)$ | ...absolutely continuous functions, 84 |
| :---: | :---: |
| $\mathfrak{B}$ | $=\mathfrak{B}^{1}$ |
| $\mathfrak{B}^{n}$ | $\ldots$. Borel $\sigma$-field of $\mathbb{R}^{n}, 260$ |
| $\mathfrak{C}(\mathfrak{H})$ | $\ldots$. set of compact operators, 128 |
| $C(U)$ | $\ldots$. set of continuous functions from $U$ to $\mathbb{C}$ |
| $C_{\infty}(U)$ | $\ldots$. . set of functions in $C(U)$ which vanish at $\infty$ |
| $C(U, V)$ | $\ldots$. set of continuous functions from $U$ to $V$ |
| $C_{c}^{\infty}(U, V)$ | $\ldots$. set of compactly supported smooth functions |
| $\chi_{\Omega}($. | . characteristic function of the set $\Omega$ |
| dim | $\ldots$. . dimension of a linear space |
| $\operatorname{dist}(x, Y)$ | $=\inf _{y \in Y}\\|x-y\\|$, distance between $x$ and $Y$ |
| $\mathfrak{D}$ (.) | ...domain of an operator |
| e | $\ldots$.. exponential function, $\mathrm{e}^{z}=\exp (z)$ |
| $\mathbb{E}(A)$ | $\ldots$...expectation of an operator $A, 55$ |
| $\mathcal{F}$ | ... Fourier transform, 161 |
| H | ...Schrödinger operator, 221 |
| $H_{0}$ | . . . free Schrödinger operator, 167 |
| $H^{m}(a, b)$ | ... Sobolev space, 85 |
| $H^{m}\left(\mathbb{R}^{n}\right)$ | . Sobolev space, 164 |
| hull(.) | . . . convex hull |
| $\mathfrak{H}$ | ... a separable Hilbert space |
| i | $\ldots$ complex unity, $\mathrm{i}^{2}=-1$ |
| II | ...identity operator |
| $\operatorname{Im}($. | . . . imaginary part of a complex number |
| inf | . . .infimum |
| $\operatorname{Ker}(A)$ | $\ldots$...kernel of an operator $A, 22$ |

| $\mathfrak{L}(X, Y)$ | set of all bounded linear operators from $X$ to $Y, 23$ |
| :---: | :---: |
| $\mathfrak{L}(X)$ | $=\mathfrak{L}(X, X)$ |
| $L^{p}(X, d \mu)$ | $\ldots$.. Lebesgue space of $p$ integrable functions, 26 |
| $L_{l o c}^{p}(X, d \mu)$ | . . . locally $p$ integrable functions, 31 |
| $L_{c}^{p}(X, d \mu)$ | $\ldots$. . compactly supported $p$ integrable functions |
| $L^{\infty}(X, d \mu)$ | ... Lebesgue space of bounded functions, 26 |
| $L_{\infty}^{\infty}\left(\mathbb{R}^{n}\right)$ | ... Lebesgue space of bounded functions vanishing at $\infty$ |
| $\ell^{1}(\mathbb{N})$ | $\ldots$...Banach space of summable sequences, 13 |
| $\ell^{2}(\mathbb{N})$ | $\ldots$. . Hilbert space of square summable sequences, 17 |
| $\ell^{\infty}(\mathbb{N})$ | $\ldots$...Banach space of bounded summable sequences, 13 |
| $\lambda$ | . . . a real number |
| $m_{a}(z)$ | $\ldots$. Weyl m-function, 199 |
| $M(z)$ | ... Weyl $M$-matrix, 211 |
| max | ...maximum |
| $\mathcal{M}$ | ... Mellin transform, 251 |
| $\mu_{\psi}$ | ...spectral measure, 95 |
| $\mathbb{N}$ | ...the set of positive integers |
| $\mathbb{N}_{0}$ | $=\mathbb{N} \cup\{0\}$ |
| $o(x)$ | ... Landau symbol little-o |
| $O(x)$ | . . . Landau symbol big-O |
| $\Omega$ | . . . a Borel set |
| $\Omega_{ \pm}$ | ... wave operators, 247 |
| $P_{A}($. | $\ldots$..family of spectral projections of an operator $A, 96$ |
| $P_{ \pm}$ | $\ldots$. projector onto outgoing/incoming states, 250 |
| $\mathbb{Q}$ | . . . the set of rational numbers |
| $\mathfrak{Q}($. | ...form domain of an operator, 97 |
| $R(I, X)$ | ... set of regulated functions, 112 |
| $R_{A}(z)$ | $\ldots$. resolvent of $A, 74$ |
| $\operatorname{Ran}(A)$ | $\ldots$. range of an operator $A, 22$ |
| $\operatorname{rank}(A)$ | $=\operatorname{dim} \operatorname{Ran}(A)$, rank of an operator $A, 127$ |
| $\mathrm{Re}($. | ... real part of a complex number |
| $\rho(A)$ | $\ldots$. resolvent set of $A, 73$ |
| $\mathbb{R}$ | . . . the set of real numbers |
| $S(I, X)$ | $\ldots$. . set of simple functions, 112 |
| $\mathcal{S}\left(\mathbb{R}^{n}\right)$ | $\ldots$. set of smooth functions with rapid decay, 161 |
| $\operatorname{sign}(x)$ | $\ldots+1$ for $x>0$ and -1 for $x<0$; sign function |
| $\sigma(A)$ | $\ldots$..spectrum of an operator $A, 73$ |
| $\sigma_{a c}(A)$ | $\ldots$..absolutely continuous spectrum of $A, 106$ |
| $\sigma_{s c}(A)$ | $\ldots$. singular continuous spectrum of $A, 106$ |
| $\sigma_{p p}(A)$ | $\ldots$. pure point spectrum of $A, 106$ |
| $\sigma_{p}(A)$ | $\ldots$. point spectrum (set of eigenvalues) of $A, 103$ |
| $\sigma_{d}(A)$ | $\ldots$. discrete spectrum of $A, 145$ |
| $\sigma_{\text {ess }}(A)$ | $\ldots$. essential spectrum of $A, 145$ |

| $\begin{aligned} & \operatorname{span}(M) \\ & \sup \end{aligned}$ | ...set of finite linear combinations from $M, 14$ <br> ...supremum |
| :---: | :---: |
| $\operatorname{supp}(f)$ | $\ldots$.. support of a function $f, 7$ |
| $\mathbb{Z}$ | . . . the set of integers |
| $z$ | ...a complex number |
| $\sqrt{z}$ | $\ldots$. square root of $z$ with branch cut along ( $-\infty, 0$ ] |
| $z^{*}$ | ... complex conjugation |
| $A^{*}$ | $\ldots$. . adjoint of $A, 59$ |
| $\bar{A}$ | ...closure of $A, 63$ |
| $\hat{f}$ | $=\mathcal{F} f$, Fourier transform of $f, 161$ |
| $\check{f}$ | $=\mathcal{F}^{-1} f$, inverse Fourier transform of $f, 163$ |
| \||.|| | $\ldots$... norm in the Hilbert space $\mathfrak{H}, 17$ |
| $\\|.\\|_{p}$ | $\ldots$... norm in the Banach space $L^{p}, 25$ |
| $\langle., .$. | ...scalar product in $\mathfrak{H}, 17$ |
| $\mathbb{E}_{\psi}(A)$ | $=\langle\psi, A \psi\rangle$, expectation value, 56 |
| $\Delta_{\psi}(A)$ | $=\mathbb{E}_{\psi}\left(A^{2}\right)-\mathbb{E}_{\psi}(A)^{2}$, variance, 56 |
| $\Delta$ | ... Laplace operator, 167 |
| $\partial$ | . . . gradient, 162 |
| $\partial_{\alpha}$ | ... derivative, 161 |
| $\oplus$ | $\ldots$. orthogonal sum of linear spaces or operators, 45, 79 |
| $M^{\perp}$ | ...orthogonal complement, 43 |
| $A^{\prime}$ | ... complement of a set |
| $\left(\lambda_{1}, \lambda_{2}\right)$ | $=\left\{\lambda \in \mathbb{R} \mid \lambda_{1}<\lambda<\lambda_{2}\right\}$, open interval |
| [ $\lambda_{1}, \lambda_{2}$ ] | $=\left\{\lambda \in \mathbb{R} \mid \lambda_{1} \leq \lambda \leq \lambda_{2}\right\}$, closed interval |
| $\psi_{n} \rightarrow \psi$ | $\ldots$... norm convergence, 12 |
| $\psi_{n} \rightharpoonup \psi$ | ... weak convergence, 49 |
| $A_{n} \rightarrow A$ | . . . norm convergence |
| $A_{n} \xrightarrow{s} A$ | ...strong convergence, 50 |
| $A_{n} \rightharpoonup A$ | ... weak convergence, 50 |
| $A_{n} \xrightarrow{n r} A$ | .... norm resolvent convergence, 153 |
| $A_{n} \xrightarrow{s r} A$ | . . . strong resolvent convergence, 153 |
